The chairman's address by Mr. J. W. Hame (York) was read in his absence by Mr. S. T. Allen (Wolverhampton), and dealt with some of the author's experiences with various types of apparatus. In comparing the heating of ovens from the sides or the top and bottom, he said that when the joint was hung the former had advantages, but for meat cooked in drip-tins probably the latter was better. He did not think that glass windows in the oven doors were worth the extra expense, as their only utility was to view an internal thermometer, for very few people knew the correct temperatures. Many of the attached thermometers supplied were unreliable. Prominent current indicators such as illuminated glass discs, were valuable in preventing waste. Regarding utensils for use with hot-plates, he had good experience with the "Tricity" porcelain and the Carron brown-ware vessels, and for metal utensils found cast-iron with ground flat bases as good as anything. The B. & K. table cooking appliances had the advantage of one cord connector being usable with any utensil, and had proved satisfactory. There were always difficulties, however, in wiring leads conveniently to a table away from the wall, and he suggested that central indirect lighting fittings should have special connectors fitted at the bottom of the inverted bowl for the purpose. He criticised the finish of a particular make of electric fire, and in conclusion urged that electricity should be used more than it is for private washing and laundry purposes, in addition to ironing. When wiring houses, as much wiring as possible should be included to which sockets and plugs could be afterwards connected.

The discussion was opened by Mr. J. W. Beauchamp (West Ham), who thought that inspection windows were useful; two were desirable with an external lamp opposite one, as lamps inside the oven soon failed. Mr. W. Pickvance (Wrexham), who spoke later, also favoured windows, as he did thermometers, but found that internal lamps lasted well, but Mr. Farndon (West Ham), and Mr. Allen were against their use. Mr. P. E. Rycroft (Heston and Isleworth), considered that the electric iron was the best introduction to domestic uses of electricity, and suggested giving irons to consumers as a substitute for discounts. Mr. W. H. Cooke (Luton), preferred side to top and bottom heating, an opinion shared by Mr. W. Travis (Brompton and Kensington), who advocated a central research bureau in electric cooking. Radiant heat was best for roasting, and "black" heat for pastry. Several speakers regretted that the water-boiling problem had not been treated in the address. Mr. Allen praised the Belling type of heater, and considered aluminium utensils with ground bottoms the best, the bottom was slightly concave when cold, but flat when hot. He wired a heating circuit and plug at a rental of 1s. per annum to encourage the heating load. Mr. A. Nichols Moore (Newport) had found that pressure variations affected cookers more on D.C. than on A.C. circuits. Mr. R. S. Downe (Brompton and Kensington), spoke of the desirability of familiarising the public with cooking otherwise than by coal, and thought that it was well worth while standardising cookers and ovens. The average consumption of a number of complete family cooking outfits in his district was  $1\frac{1}{2}$  units per head per day. Mr. F. Fardon, who was one of several speakers who were enthusiastic in supplying irons on trial as an introduction to domestic uses of electricity, described a new pattern of plug which has been developed by A. P. Lundberg & Sons, in conjunction with the West Ham staff, the main features of the apparatus being the contact pins and terminals, which are made in one solid piece, two set-pins being provided in the terminal for securing good contact with the flexible wire, thus overcoming the possibility of over-heating at the joints forming the contacts on the usual type of plug. The plug top is made in halves, clamped together by means of brass set pins, the result being to form a cord-grip on the braiding of the flexible wire. Mr. A. H. Seabrook (Marylebone), referred to the desirability of developing a thermostatic control of oven heating which would do away with individual switching, so that the cook had simply to turn a pointer to the temperature required, and the thermostat would maintain the oven at that temperature. He firmly believed in properly illuminated indicators, showing the position of switches. He did not consider fixing the switches and fuses on the cooker was good practice.

They should be mounted on a separate control board. He agreed with the author that cast-iron pots with turned bottoms proved the best for hot-plate heating. He emphasised the necessity of fixing to each cooker, either a rapid boiler or a separately heated kettle for small quantities of water required quickly. Either of these heaters would supply hot water at a quicker rate than was obtainable by gas.

## THE ELECTRICAL CONTRACTORS ASSOCIATION

THE annual banquet of this Association took place on Wednesday, April 29th, at the Grand Hotel, Leicester. Mr. S. H. Webb, the President of the Association, presided, and his name was coupled with the toast of the Association proposed by Mr. Councillor Squire, of Leicester. In the course of his remarks, Mr. Squire said that electrical contractors could deal with matters affecting their trade much better as an association than individually, and that the Association had done a great deal towards maintaining the dignity of the trade and upholding a high standard. Their President was a working President, who had visited almost every branch of the Association. In the course of his reply, the Chairman maintained that municipal bodies ought to be limited in their scope by the question as to whether the community as represented by the municipality could render better service than private enterprise, or only equally well. In the latter event the municipality ought not to step in. Other points referred to were Mr. Marryat's guarantee of work scheme, which the Chairman said would attach more value to the letters "E.C.A.," and the I.M.E.A. Bill.

Mr. E. C. Wallis proposed the toast of the Institution of Electrical Engineers, the Association of Municipal Electrical Engineers, and Kindred Associations, which was replied to by Mr. T. R. Smith, Borough Electrical Engineer of Leicester, who gave some figures and information relating to the Leicester Corporation Electricity Works, and Mr. W. H. Allen, Borough Electrical Engineer of Loughborough. Mr. Councillor H. L. Harrison, of Hull, Chairman of the Northern Section of the E.C.A., proposed the toast of the President, to which Mr. Webb replied. Mr. Hurley then proposed the health of the Secretary, Mr. L. G. Tate, and in replying Mr. L. Tate referred to his work in connection with the Association as a work of love. An excellent musical programme was arranged by Mr. W. Grocock, F.R.C.O., L.R.A.M.

## ELECTRIC TRACTION NOTES

Col. E. Druitt's Board of Trade Report on an accident which occurred on the Rochdale Tramways on February 14th, when a car attained a high speed descending an incline, and subsequently left the rails on a curve, colliding with a tramway standard and dashing into a shop window, has now been issued. The inspector attributes the accident to the driver allowing too high a speed to be attained before applying his magnetic brake sufficiently, and when putting it on the last notch suddenly skidded the wheels. It was impossible to find whether there was any defect in the brake control owing to damage done by the collision, but it is stated that the driver had not previously tested the brake. The design of the sand-boxes is criticised.

In the course of a discussion in the Dover Council on the rates to be charged by the Electricity Department to the Tramways Department for current used by the tramways, it was stated that the use of meters on the cars had led to such economy in current consumption that the total amount was reduced below the figure at which a reduced charge per unit was made, and therefore energy was charged for at 2½d. per unit, instead of 2½d. which had been the charge during previous years, when, without meters, the consumption was greater. A motion to charge at the 2½d. rate was defeated.

The Bristol Corporation Tramways Bill, which proposed to give the Corporation authority to work the undertaking of the Bristol Tramways Co. when it should be acquired by the Corporation under the provisions of the Tramways Act, was considered by a House of Lords Committee last week. After a considerable amount of evidence, the Committee decided that the Corporation must make up its mind either to purchase the tramways, which it has the option to do in May next year, or to drop the present bill and come to Parliament at a later period, when it had made up its mind on the question. As the bill was originally drafted, the Corporation was not under an obligation to purchase the tramways.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Demonstrations have been given this week before some Russian officers, between Marconi House and the Savoy Hotel, of the new system of wireless telephony which Mr. Marconi has lately been at work on. It is understood that this system, with which many successful experiments were recently made on Italian warships, is being introduced into the Italian navy, and is being considered by other foreign Powers. It is described as a simple, practical system, with apparatus of small power, and, as at present constructed, will send messages between fifty and a hundred miles or more. With larger apparatus it is anticipated that longer distances will present no obstacle, and that a wireless telephone service from London to New York should be practicable.

The Postmaster-General, in his speech last Thursday introducing the Post Office Estimates, stated that the chief cause of the increased figure (£26,150,000) which he had to put forward (an increase of £1,770,000 over that of last year) was the rise in salaries of Post Office employees. He mentioned that the telegraphs were run at a loss of £350,000, but that there was a profit of £300,000 on the telephone service. On the average, every 6d. telegram cost 11d. to send. He hoped that some of the telegraph expenses would be lightened by replacing this service in part by the telephone. He spoke of the rapid development of the telephone service, and the difficulty in training workers to look after it in sufficient numbers. The telephones in London had increased by 13,000 in a year, and were now 243,000 in number. He hoped this year to open four new exchanges, and to spend £750,000 in extensions in London and £1,650,000 in the provinces during the coming year. The intertown communication system, as used between Liverpool and Manchester, was to be applied to Leeds and Bradford. Automatic exchanges were in progress at Accrington, Darlington, Stockport, and Leeds. If these were successful they would be introduced all over the kingdom, and eventually, if possible, in London. He was unable to make an announcement regarding the new telephone charges. With regard to wireless telegraphy, Mr. Hobhouse said that he hoped to rearrange wireless stations for internal communication in a manner leading to extensive developments and cheaper communication. There were nine ship-to-shore stations, and more were coming into existence at Valencia and Stonehaven. Erection of one of the home stations for the Imperial wireless stations was begun, and sites were acquired at Cairo. The Indian station was to be at Pooná. These were to be established by the Marconi Co., but the Post Office was still free to hand over the others to any other company.

The Local Government Board has sanctioned a loan of £192,428 for the purchase of the National Telephone Co.'s plant in the Hull area from the Postmaster-General. The period of repayment is to be nineteen years. The purchase was completed yesterday.

At the meeting of the Indo-European Telegraph Co. it was announced that the additional circuit from London to Teheran was now an accomplished fact, and would shortly be linked up to the additional wire to Karachi.

The Bagdad-Bassorah line has been restored, as well as the Persian line, between Behbahan and Abwaz.—The Mexican lines were restored on April 29th to Mexico City *via* Salina Cruz, and also to Coatzacoalcas and Tehuantepec.—The *via* Galveston route is also again available.—Private telegrams in clear and code language are also once more admitted to Vera Cruz.—The Saigon-Bangkok line was down on May 1st, and on the 5th inst traffic for Siam "*via* Moulmein" was subject to long delay, owing to the bad condition of the lines.

**A Claim for Commission.**—At the Lord Mayor's Court on Friday, a claim was made by Messrs. L. Cahn & Co., stock-brokers, against the Dubilier Syndicate and M. Mclean for commission alleged to be due in connection with an introduction which led to licences under certain patents of the Syndicate being taken up by the General Electric Co.

**Charging Tariffs for Electric Vehicles.**—The suggestions of the Electric Vehicle Committee regarding prices for motor vehicle battery charging have been adopted at Marylebone, Stoke-on-Trent, and Heston and Isleworth. The charge is to be 1d. per unit during non-peak hours, or ½d. between 11 p.m. and 6 a.m., by special arrangement, with a minimum of 2s. when cars are brought to the station. A discount of 20 per cent. is given for current purchased for resale, and in the case of Marylebone there is a special scale of discounts for large consumers.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published April 30th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

**7,898/13. Increasing Strength of Magnets.** P. MAY. A method of increasing the magnetic flux beyond the ordinary point of saturation by heating the core of the magnet at suitable points. A horse-shoe magnet is heated at the bend; a bar-magnet, at the middle. Heating may be effected either directly, or by the eddy currents induced by an A.C. coil wound round the core at the desired place. It is claimed that the magnetisation can be increased about 30 per cent. by this means.

**8,249/13. Train Control.** E. C. R. MARKS (*E. G. Mascarenhas*). This method of preventing trains from overrunning signals is used in conjunction with the make and break, controlled from the semaphores in the ordinary signalling system. Short contact rails are provided at sides of track, and contact levers are provided on the engine to engage with these rails. A solenoid on the engine controls the operation of the air valve for braking. This solenoid is energised either through a relay, when the external circuit, containing the semaphore make and break, is in the danger position, or by the action of a centrifugal governor which closes the circuit when the train speed exceeds a certain safe maximum. If, however, the speed of the engine is below a certain value, the solenoid circuit is kept open by the governor, so that the train can pass the danger signal provided its speed has been reduced sufficiently. Eleven figures.

**11,017/13. Preparation of Ductile Tungsten.** WESTINGHOUSE METALLFADEN GLUHLAMPENFABRIK GES. This process consists in heating the metal to a high temperature and allowing it to cool slowly under pressure, *e.g.*, introduce the metal into a molten mass or heated mould, which exerts the desired pressure on cooling. Sintered tungsten is mixed with a quantity of thermit and ignited. To prevent the tungsten being dissolved, it may be enclosed in a tube of refractory material or covered with an infusible oxide, or the metal used for exerting the desired pressure may be saturated with tungsten. The process is also applicable to molybdenum.

**26,442/13. Speed Regulation of Rolling-mills.** W. R. WEBSTER. The relative speeds of two rolling-mills are regulated so as to keep a constant tension in the stock passing between them. One of the mills is fixed, the other is mounted on slides. The distance between the mills is regulated by a plunger working in a pressure chamber. Variation in the relative speeds of the motors will cause the movable mill to change its position on the slides. This motion operates a rheostat which corrects the speed of the movable mill and brings the tension in the stock back to normal. Two figures.

**29,059/13. Sparking Plug.** C. SPADA. The points of the plug can be cleaned whilst the engine is running. One electrode is in the form of a central vertical spindle, and the other is formed by inward projections from the body of the plug. The vertical electrode is held in position by a spring, and cleaning is effected by depressing the spindle, so as to bring the two electrodes together, and rotating. Five figures.

**895/14. Automatic Telephone System.** WESTERN ELECTRIC CO. (*F. T. Woodward*). The principal feature of this specification is a device to impress a "ringing" tone upon the calling line so that the caller will know that the called line is being signalled. A "busy" tone is produced upon the calling line if the desired line is engaged. These two devices are located at the first selector switch through which communication may be established. Five figures.

**6,353/14. High-pressure Arc Lamp.** E. WEINTRAUB. In this lamp the anode is a flat spiral of tungsten wire, and the cathode, mercury. Precautions are taken to prevent condensed mercury falling on to the anode. The voltage required for starting the arc is less than the normal working voltage.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** BRYAN, GOLDING, and PEARCE [Arc lamps for projection apparatus] 8,968/13.

**Dynamos, Motors, and Transformers:** WHITE and BACON [Brush-holders] 9,094/13; HUNT and SANDYCROFT, LTD. [Dynamo-electric machines] 9,260/13, 9,261/13; GIRARDEAU [High-frequency generators] 12,809/13; B.T.-H. Co. and BROWN [Electrical driving of reciprocating machinery] 14,049/13; B.T.-H. Co. (*G.E.C., U.S.A.*) [Electric transformers] 18,663/13.

**Electrometallurgy and Electrochemistry:** S<sup>oc</sup>. G<sup>énérale</sup> DES NITRURES [Heating of electrical furnaces] 24,347/13; BRONN and SCHEMMANN [Protecting furnace electrodes] 29,259/13.

**Ignition:** EICHBAUER [Ignition device for bombs and explosive mines] 8,371/13; VARLEY [Starting and igniting systems for the engines of motor vehicles] 8,679/13, 119/14.

**Incandescent Lamps:** DOWNES and VENNING [Cut-outs for instruments, glow lamps, &c.] 9,100/13; GARDE [Candle lamp] 24,130/13.

**Switchgear, Fuses, and Fittings:** HOPE and THOMAS [Enclosed switches] 9,212/13; MILLER and BOOTHMAN [Regulating switches] 5,505/14.

**Telephony and Telegraphy:** McKENNA (*Fankhauser*) [Telegraphones] 5,958/13; JENNINGS [Loud-speaking telephone] 9,904/13; SIEMENS and HALSKE A.-G. [Circuit arrangements for automatic and semi-automatic telephone systems] 14,487/13, 29,049/13, 1,792/14; THOMPSON (*Soc. Anon. des Télégraphes Edouard Belin*) [Resistance device for microphones and the like] 17,562/13; HADDAN (*Reineke*) [Relays for weak, undulating currents] 22,943/13; EASTERN TELEGRAPH CO. and RYAN [Duplex telegraphy] 25,591/13; MILLERSH-JACKSON (*Signal Ges.*) [Radio-telephone stations] 27,175/13; FADER and TIBB [Call registering telephone] 29,864/13.

**Traction:** HARTFORD and MASTRANGEL [Electrical installation for motor vehicles] 8,792/13; JOHNSON [Automatic signalling devices] 26,358/13.

**Miscellaneous:** ROLFE [Field magnets] 1,222/13; WALL [Electrically operated drill] 9,893/13; BLOXAM (*Oesterreichische Siemens-Schuckertwerke and Regal Patente Ges.*) [Picture-reproducing machines] 10,460/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, &c.:** SOC. ANON. LE CARBONE [Electrical connections] 8,695/14.

**Dynamos, Motors and Transformers:** LJUNGSTROM [Electrical machines] 4,979/14; ALLMANN SVENSKA ELEKTRISKA AKTIEBOLAGET [Alternating current machines having bar winding] 8,565/14; SOC. ANON. DES AUTOMOBILES and CYCLES PUGBOT [Electric lighting plant control] 9,175/14.

**Telephony and Telegraphy:** FRATELLI MARZI DI G. B. [Microphones] 2,624/14; SIEMENS and HALSKE AKT.-GES. [Circuit arrangements for telephone systems] 8,800/14.

**Traction:** YSEBODT [Block signalling apparatus] 8,983/14.

**Incandescent Lamps:** BENJAMIN [Lamp sockets] 7,298/14.

**Miscellaneous:** A. E. G. [Feed mechanism for type-writers] 4,357/14; SPRENGER [Electric heating devices] 8,719/14.

The following Amended Specifications may now be obtained:—

**Arc Lamps:** BLONDEL [Arc lamps] 4,677/06.

**Traction:** INTERNATIONAL P. A. Y. E. TRAMCAR CO. [Railway and similar vehicles] 14,584/12.

### Restoration of Lapsed Patent

**26,042/07. Fire Indicator for Ships.** An order has been made, restoring this patent to W. Rich. Air is drawn, by an electric fan, through a number of pipes, from different parts of the ship, and led to an observation box. Smoke issuing from one or more of the pipes indicates fire. The fan is driven intermittently by an electric motor, which is switched on at intervals by clockwork. An electric lamp is included, so that the apparatus can be used at night. Provision is also made for extinguishing the fire by blowing steam down the pipes.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors and Transformers:** W. E. LAKE (*Bissel Co.*) [Self-contained arrangement of motor and controlling mechanism] 758/09; SIMMS [Safety spark-gap device for brush holders of h.t. machines] 1,263/09; LAKE (*Bissel Co.*) [Controller for small motors] 13,734/09.

**Instruments and Meters:** SIEMENS BROS. [Maximum demand indicator] 878/08.

**Switchgear, Fuses and Fittings:** E. A. CAROLAN (*G.E.C., U.S.A.*) [Combined switch and cut-out for high-tension lighting systems] 1,066/05; B.T.-H. Co. (*G.E.C., U.S.A.*) [Three-pole circuit-breaker with overload and no-load release] 952/06; MORRIS and ATR. [Quick-break switch] 1,354/07; BRACKENSIECK [Automatic interrupter for electric signs] 16,885/09.

**Telephony and Telegraphy:** STOLZ [Telephone for the deaf] 13,875/08.

**Traction:** B.T.-H. Co. (*G.E.C., U.S.A.*) [Series-parallel motor control for petrol-electric or steam-electric cars] 1,279/07; MUNRO [Trolley head for overhead conductors] 1,077/09.

**Miscellaneous:** G. S. TIFFANY [Electrically operated clock with compensated pendulum] 1,258/04; W. M. BARNES [Ironing machines] 1,284/06; LOEHL [Electrically illuminated clocks] 785/09.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 263. —

01

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**BATTERY CHARGING GENERATORS.**—The subject of small generators (from 0.22 to 2.52 kw.) for the charging of 50- or 100-volt batteries is dealt with in a new illustrated pamphlet from the British Thomson-Houston Co., Ltd. (Rugby), who have standardised a special line of machines for the purpose, the good points of design of which are fully set forth in the specification contained in the pamphlet.

**METAL FILAMENT LAMPS.**—An effective coloured postcard from the Edison & Swan United Electric Light Co. (Ponder's End, Middlesex) reproduces a striking poster design, in which Aladdin is carrying a Royal Ediswan drawn-wire lamp nearly as big as himself, which is indeed wonderful in that it is brilliantly illuminated without being connected to any circuit.

**DIAMOND DIE POLISHING MACHINES.**—A pamphlet from Werths & Co. (41 Aldersgate Street, E.C.), describes the Poppe patent automatic machine for polishing diamond dies for wire drawing. This machine can polish 10 dies at once with an accuracy unattainable by the older methods. A number of these machines are in use at drawn wire lamp factories at home and abroad.

**HOLOPHANE FITTINGS, &c.** A new leaflet from Krupka & Jacoby, Ltd. (26 to 36 Chapter Street, Westminster, S.W.), illustrates a number of special fittings for use with holophane glassware, including galleries for carrying these reflectors.

**FANS.**—A full line of electric fans, including a new inexpensive design of 12-inch D.C. swivel and trunnion pedestal fan, is dealt with in another list from the same firm.

**TELEPHONES.**—A hygienic glass telephone mouthpiece is dealt with on a card from the Sterling Telephone and Electric Co., Ltd. (210-212 Tottenham Court Road, W.).

**WIRELESS TELEGRAPH APPARATUS.**—A new catalogue of wireless telegraph apparatus, suitable for equipments of great variety of styles and sizes, has been issued by A. W. Gamage, Ltd. (Holborn); complete portable and other sets are listed, as well as a large range of separate pieces of apparatus, accessories, &c. With this list we have received a copy of the second edition of Gamage's Directory of Experimental Wireless Stations in the United Kingdom.

**STRIP LIGHTING.**—A leaflet from the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), gives notice of reduced prices for both the "Narro Striplite" and "Aluminium Striplite" reflectors for strip lighting by tubular lamps.

**Visit to the Ediswan Works.**—The members of the University of Birmingham Engineering Society paid a visit on May 1st to the works of the Edison & Swan United Electric Light Co., Ltd. In the Lamp Department visitors were shown glass making, bulb blowing, tube drawing, manufacture of carbon filaments, flashing filaments, preparing and mounting metal filaments, jointing filaments, stem making, sealing-in filaments, exhaustion of lamps, capping, stamping and testing of the finished lamp, and the new half-watt lamp was also seen alight. In the Engineering Department the complete manufacture of high and low tension switchboards, circuit breakers, oil switches, transformers, generator rheostats, motor control gear-holders, switches, plugs, and other electrical accessories was inspected, and the turret shop, brass shop, and foundry were visited, and the complete manufacture of electrical fans, and a great variety of electrical heating apparatus, including all forms of the Bastian radiators, was witnessed, as well as that of electrical piano players and other interesting articles. Tea was served in the general offices, after which Mr. J. G. Pearce, the Members' Secretary, expressed a vote of thanks for the educational value of the visit and their cordial reception. Mr. E. Gimingham replied on behalf of the directors and staff.

### INEXPENSIVE SEMI-INDIRECT FITTINGS

WE illustrate here two new fittings for semi-indirect lighting which the British Thomson-Houston Co. (Mazda House, 77 Upper Thames Street, E.C.) have recently added to their already long series. One of these fittings consists of three chains, a ceiling plate, and a ring to support the opal bowl. The fitting, although simple, is of graceful design. These fittings are made for single Mazda lamps, or for clusters of four or six, and in diameters ranging from 10 in. to 19 in. The prices range from 17s. 6d. upwards,

FIG. 1.—SEMI-INDIRECT FITTING WITH SHALLOW OPAL BOWL FOR 4 TO 6 LAMPS.

FIG. 2.—SINGLE LAMP SEMI-INDIRECT FITTING WITH VELURIA HEMISPHERE.

complete with glassware and lamp-holders. The other fitting is almost as inexpensive, the prices in this case ranging from 18s. This employs a Veluria hemisphere reflector bowl, and is made either with central chain or tube suspension. The glassware is held by means of thumbscrews on three arms radiating from the central suspension. Veluria hemisphere fittings are supplied in various diameters to take single Mazda lamps of from 30 to 400 watts.

**Half-watt Lamps for Exhibition Lighting.**—The main lighting for the Bristol International Exhibition is to be effected by half-watt lamps, which will be employed exclusively by the Electrical Engineering and Equipment Co. (109-111 New Oxford Street, W.C.), who have the contract for the whole of the electrical work, both lighting and power, including switchgear, mains, feeders, and services, outside and interior lighting. The firm write us that since the advent of the half-watt lamp they would not think of using arc lamps for an installation like this, owing to the trouble and expense entailed by their cleaning, re-carboning, and general maintenance. They claim to be the first firm in this country to carry out an important lighting installation of this kind with half-watt lamps.

**Condenser Protective Gear.**—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), have concluded arrangements to supply the Moscicki condenser and Giles valve for this country, in those cases where the protective gear forms part of the general scheme of switchgear. For South Africa, China, excluding Southern Manchuria, Australia, and India, they have the sole right of sale and representation. The General Electric Co. are now prepared to quote for such gear for the protection of overhead and underground lines and power houses against lightning surges, pressure rises, and similar contingencies, embodying these special schemes of protection, in addition to their Standard Lightning Arrester equipments, which are now in use all over the world.

Such a "Just What's Wanted"

article as

## The New "BELLING RING"

(Reg. Design 634,028, patent applied for)

Been put on the Market.

IT DOES ANYTHING the ordinary gas ring does—just as quickly—and more economically.

IT BOILS (2 pints in 6 mins.)  
IT TOASTS (4 pieces per minute.)  
IT FRIES. IT GRILLS.

Using all the ordinary existing Kitchen Utensils.

It does not matter what's spilt on it—Water, Grease, Dirt,—nothing does it any damage.

We guarantee it for one year of average household use,  
—it will probably last for three.

IT IS THE QUICKEST SELLER  
ever yet introduced to the Electrical business.

ITS OBVIOUS UTILITY ensures INSTANT PURCHASE.

Do you realize that with a little effort you could easily  
Sell one of these Rings straight away to, say, 50% of  
your Consumers?

JUST WORK OUT WHAT

EARLY MORNING LOAD  
THIS WOULD CREATE!!!

Everyone would Boil their Kettle for the Early Morning  
Tea. Two Rings would Cook all the Breakfast.

PRICE — 6-inch Ring 1500 watts, complete with control  
panel, fitted with switch, fuse, and terminals for mains,  
22/6 subject.

### SEND FOR A SAMPLE AT ONCE

TAKE IT TO PIECES (by removing just 8 screws), examine its entire construction, remember that the perforated top is made from solid nickel chromium (so that it does not flake away or oxidize) and you cannot but be convinced of its reliability.

It is made on our patented construction of running a non-corroding wire in FREE AIR, and supported at suitable intervals by projection from a refractory fireproof base underneath. The channels in this base carry off any liquids accidentally spilt on the wire.

There are no "air pockets," no points of "bad heat conductivity," no "uneven temperatures" or strains on the resistance wire—in fact no excuse of any kind for breaking down.

You know who we are—  
You know our usual lines of business—  
You know we have maintained a high standard  
in our goods—  
You know we have done exceeding well with  
"Fires" this last Season.

DO YOU THINK WE SHOULD RISK  
OFFERING YOU A NEW ARTICLE  
WHICH WE WERE NOT PERFECTLY  
SURE WAS A SOUND ONE?

Write us, 'phone us, OR COME AND SEE US, the latter for preference. We are ordinary people, with simple ways, and we like to discuss practical points with practical men. Our acting Partner, Mr. C. R. Belling, is always personally at your service.

## BELLING & CO.

Electric Cooking and Heating Specialists,  
EDMONTON - - - LONDON, N.

P.S. We also have a fine line in "Grillers."

### HOTEL LIGHTING

ONE instance of the many ways in which Osram half-watt lamps can be effectively employed for attractive outside lighting is afforded by an installation at The Mitre Hotel, Tooting. Here three Osram half-watt lamps have displaced

A HALF-WATT LAMP INSTALLATION.

the arc lamps previously used, and, as may be seen from the illustration, a remarkably striking effect is produced. The lamps look well in the General Electric Co.'s "Vintner" lanterns, which are of one of the extensive range of specially-ventilated lanterns designed for use with these lamps. Each of the lamps is of the 500-watt size, requiring 65 volts, so that the three are conveniently run in series. The work was carried out by Mr. A. R. Ashmore, Electrical Engineer, 4 Station Parade, Balham, S.W.

### AN ELECTRICAL ADVERTISING DEVICE

WE had the opportunity of inspecting, at the recent Advertising Exhibition in Holland Park Hall, London, some ingenious machines in which electricity is utilised in the attractive display of advertisements. The Graham-King Auto-Electric Advertisers take the form of a compact cabinet, through the glass front of which various advertisements are made to appear at intervals. The mechanism, which ran very sweetly, was driven by a  $\frac{1}{10}$ -h.p. D.C. motor, and consists essentially of a revolving drum driven by friction rollers through worm-gearing, and carrying at each end arms for lifting the posters into position ready for passing over the drum to the front of the cabinet. Two strip lamps are situated at each side of the displayed poster, but invisible from the front, and these are switched on automatically as soon as each poster is in position. The arrangement of the posters in the cabinet assists the effective illumination, and the effect is that of a framed picture. A clock is fitted immediately above the front of the cabinet, and serves the double purpose of drawing attention to the machine and switching the motor into and out of operation at the desired times. The standard cabinets will take thirty-two posters of either crown, double crown, or double royal size, but we understand they can also be built to special requirements.

**New Showrooms.**—The Edison & Swan United Electric Light Co., Ltd., advise us that they will be opening new West End showrooms at 71 Victoria Street next week. These will contain an extensive show of all Ediswan electrical accessories, "Royal Ediswan" drawn-wire and carbon lamps, electric heaters, fans, fancy fittings, glass ware, suction cleaners, flat irons, cooking utensils &c.

**"Rands Plant."**—This is the title of a new monthly periodical, price 2d., which is being published by Paul W. Rands, Caxton House, Westminster, and forms a register of plant for sale at low price, and ready for immediate dispatch. A large number of motors, dynamos, complete generating sets, engines, boilers, various electrical and engineering goods and also motor-cars, are offered for sale.

**Electric Signs.**—In a case last Thursday Mr. Justice Astbury was called upon to decide whether the erection of an electric sign on a certain building at the corner of Shaftesbury Avenue and Piccadilly Circus, was prohibitable on the ground of being an alteration in the elevation or architectural decoration, under the terms of a London County Council lease. His Lordship held that such temporary advertisements, which could be removed at any time, did not constitute a breach of the covenant in question.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Bexhill.**—£2,500 is to be spent on feeders and distributors to an outlying district, and a booster.

**Bexley.**—The U.D.C. invite tenders for controllers, &c. (See advertisement on another page.)

**Devonport.**—Cables, wires, and meters. Form of tender from J. W. Spark, Borough Electrical Engineer, Newport Street, East Stonehouse. Tenders by May 12th.

**Hindley.**—Tenders are invited by the U.D.C. for four-core L.T. lead-covered and armoured cable, joint-boxes, and feeder pillars. Particulars from O. P. Abbott, Council Offices. Tenders by May 18th.

**London: Hampstead.**—It has been decided to put in additional plant at the station at a cost of £7,600, to extend the mains (£2,604), and to erect a new sub-station (£1,068).

**Lytham.**—As reported in our issue for April 23rd, Lytham is to take a supply of electricity in bulk from St. Anne's-on-Sea. A Local Government Board inquiry to sanction a loan of £23,700 by the Lytham Council has been held. The initial expenditure will only be about £10,000 for three transforming stations and mains.

**Rotherham.**—A Local Government Board inquiry was held last week with regard to an application for sanction to borrow £19,956 for extensions. The estimate includes a 2,000-kw. alternator (£7,350), steam piping (£1,536), 1,000-kw. rotary and transformers (£2,600), switchgear and cables (£1,250), overhead crane (£300), and mains extensions for three years (£6,000).

**West Bromwich.**—Tenders are to be invited for a storage-battery and booster at the electricity works, at a cost not exceeding £5,000.

**York.**—The Electricity Committee has approved a report by the City Electrical Engineer, Mr. Hame, recommending a 1,000-kw. high-tension feeder on the solid system to a new sub-station at a cost of £5,500; a rotary-converter sub-station at about £3,000; further mains and transformers required during the next twelve months at £3,700; £3,000 for new services during the future, and £1,500 for a rotary-converter and transformers at the generating station.

### Wiring

**Belfast.**—Steps are being taken to ascertain the probable cost of lighting St. Jude's Church. Rev. Canon Davis, M.A.

**Bognor.**—The electric lighting of the Western Esplanade Gardens and Bandstand has been decided upon.

**Edinburgh.**—Electric lighting, power, telephone, and bell work for hostels for women students. J. King, M.A., Provincial Training College, Moray House. Tenders before May 20th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Barrow.**—New schools at Victoria and South Vickers Town. Education Committee.

**Bristol.**—Central premises for Y.M.C.A. Architects, Oatby & Lawrence.

**Dudley.**—New town hall, police buildings, school extensions, and hostel for training college. Town Clerk.

**Edinburgh.**—Cinematograph theatre in Portobello. Central Picture House Portobello Co.

**Manchester.**—Cinematograph theatre in Oxford Road. Architect, P. Hothersall, 426 Bury New Road, Prestwick.

**Powell Duffryn.**—360 dwelling houses for the Powell Duffryn Steam Coal Co. E. M. Hann, Aberdare.

## TENDERS RECEIVED AND ACCEPTED

**Bolton.**—Tenders have been accepted for six Balcke air filters, also for Ferranti single-phase transformers, and Alexander Wright CO, recorders.

**Gloucester.**—The tender of British Insulated & Helsby Cables, Ltd., has been accepted for cables for the coming year, at £630. Fifteen other firms tendered.

**Heston and Isleworth.**—Isaria, Ltd., have obtained an order

for 10 to 100 ampere D.C. ampere-hour meters, and prepayment meters.

**London: L.C.C.**—The G.E. Co.'s tender for lighting the central car repair depot and the Abbey Wood car shed, at £217, has been accepted. The other tenderers were Edison & Swan Co., at £223; and Armorduct Manufacturing Co., at £224.—The B.T.-H. Co.'s tender for carbon-filament lamps during 1914 has been accepted by the Stores and Contracts Committee.—We announced in our issue of March 5th that, in connection with the tenders for metal-filament lamps, "other than drawn," two tenders for foreign lamps had been passed over, and the lowest tender for lamps of British make had been recommended for acceptance. The Committee reports that since then circumstances have been brought to its notice, which, in its opinion, render it undesirable at the present time to accept any of the tenders received.—Messrs. Lund Bros.' tender for lighting the Upper Marylebone Street school at £294 10s. has been accepted. A lower tender, that of Napier-Kimber, Ltd., at £257, was originally accepted, but has been withdrawn.—The Asylums Committee has given the General Electric Co. the contract for the supply of Osram lamps during the current year.

**Hampstead.**—The tender of the Electrical Engineering & Equipment Co. for high-tension cables has been accepted.

**Maynooth.**—2,300 Royal Ediswan drawn-wire lamps have been ordered for Maynooth College through a Dublin firm.

**Nottingham.**—The tender of Siemens Bros. Dynamo Works has been accepted for Wotan and carbon lamps for the Electricity Department.

**Stretford.**—Bertram Thomas's tender for the lighting of the new school at Trafford Park at £293 has been accepted.

**Walthamstow.**—The U.D.C. Council has accepted the General Electric Co.'s tender for Osram lamps.

## APPOINTMENTS AND PERSONAL NOTES

Mr. H. A. Howie, Deputy Manager and Chief Assistant Engineer at Sheffield, has been appointed Borough Electrical Engineer at Walsall, in place of Mr. A. S. Barnard, whose resignation we recently recorded. The commencing salary is £500 per annum. The following were also on the short list: T. A. Kerr, Engineer and Manager, Trafford Power and Light Supply (1902), Ltd.; F. V. L. Mathias, Borough Electrical Engineer, Warrington; H. H. Perry, Resident Engineer at the Brimsdown Station of the North Metropolitan Electric Power Supply Co.; P. E. Rycroft, Engineer and Manager, Heston and Isleworth U.D.C.; and H. F. J. Thompson, Chief Assistant Electrical Engineer, Battersea.

Pending the appointment of a successor to Mr. J. A. Robertson, Mr. John H. Parker, assistant, is taking charge at Greenock.

The partnership between C. S. Vesey Brown and W. Hall, lately carrying on business as consulting engineers at Milburn House, Newcastle, has been dissolved by mutual consent.

Mr. John B. Sparks has resigned his position under Dr. H. F. Parshall, Consulting Engineer, to take up the position of Chief Electrical Engineer to the Bergwerks u. Hüttenverwaltung G.m.b.H. (Gallus Anlage 2, Frankfurt a. Main), a company owning copper, tungsten, and tin mines in Silesia and Bohemia.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £65 15s. to £66 5s. (last week, £65 10s. to £66).

**Agency.**—Nalder Bros. & Thompson, Ltd., inform us that the agreement for the agency which has been held for some years past by Messrs. Frampton & Paine, of 29 Old Queen Street, Westminster, has now expired. Pending new arrangements, all inquiries should be sent direct to Nalder Bros. & Thompson, Ltd., 97A Dalston Lane, London, N.E.

**Bankruptcies, Liquidations, &c.**—W. Walker, late of 2 and 3 Red Lion Court, trading as David Smith & Co., has been adjudicated bankrupt.—The first meeting of creditors of the Globe Association Cable & Telegraph Services, Ltd., will be held at 38 Carey Street, W.C., at 12 noon on May 12th, 1914, followed by that of the contributories at 12.30.

## LOCAL NOTES

**Aberdeen: Extensions.**—The new Oerlikon 3,000-kw. set has satisfactorily passed through the official tests.

**Blackburn: Accounts.**—The income of the Electricity Department during the year was £48,400, and expenditure £24,217. After deducting various charges, the net profit was £5,087. On the other hand, owing to the strike the Gas Committee lost over £10,000 on the year's working compared with a profit of about £10,000 for the previous year.

**Dewsbury: Opening of Extensions.**—The extensions at the Dewsbury Electricity Works, which are now complete, were inspected by members of the Corporation last Thursday. They include a 1,000-kw. Brush turbine driving two dynamos in tandem, Allen condensers, and two B. & W. boilers.

**Coventry: Bonus to Employees.**—There is a surplus for the year of £21,943; £5,000 is to be allocated to relief of rates, a bonus of £375 is to be paid to the employees in the department, and £16,250 is to be added to the reserve fund. Of the last-mentioned amount, £13,250 is to be transferred to capital account, instead of raising a loan for extensions (£2,000 for house services, £2,000 for sub-station equipment, £4,250 for cooling towers, and £5,000 for the laying of distributors from which an immediate revenue is not anticipated).

**East Ham: Relief of Rates.**—£2,000 of the Electricity Department profits has been allocated to relief of rates.

**Ely: Gas Co.'s Application for Provisional Order.**—The Gas Co.'s application for provisional order to supply electricity was the subject of a Board of Trade inquiry last week. The price of gas at Ely is 4s., less 5 per cent. for lighting, and 3s. 4d., less 5 per cent. for power. Only a very small compulsory area is scheduled. Mr. A. H. Dykes gave evidence in favour of the scheme, and referred to the reduction in standing charges which would follow the combination of electricity and gas undertakings. He said there was not sufficient scope for an independent electric light company in Ely. Although the Ely U.D.C. were withholding their consent, they were not represented at the inquiry; but there was strong opposition by the Ely and District Ratepayers' Association.

**Heywood: Bulk Supply from Bury.**—The Board of Trade has granted the Bury Corporation's application for an Order dispensing with the consent of the Lancashire Electric Power Co. for the supply of electricity in bulk to Heywood. A report of the arguments advanced during the hearing of the Board of Trade inquiry was published in our issue for November 6th, 1913, page 623. It will be remembered that one of the reasons advanced by the Lancashire Power Co. against the Board of Trade granting consent was that the offer of the Bury Corporation was lower than the rates at which similar supply was given in Bury itself. The agreement with Bury is for ten years, with the option of extending it for another five years.

**Jersey: St. Heliers.**—The Deliberative Assembly has decided to sanction the electric lighting of the town by a company.

**King's Lynn: Extensions.**—A new 400-kw. reciprocating set, condensing plant, boiler, economiser, and feed-pumps have been put in, and were formally inaugurated on Thursday, last week.

**Kingston: Councillor's Visits to Works.**—At the last meeting of the Council, Mr. Gasson, a member of the Electric Lighting Committee, moved that a member of the Council or Lighting Committee be allowed to visit the electric lighting works at any time, and complained of discourtesy on occasions of his own visits there. Mr. Edgecome, the Borough Electrical Engineer, explained that Mr. Gasson had come frequently at various times without asking for him or for the assistant in charge, and had actually gone on to the switchboard gallery to inspect the log-book. Mr. Edgecome said that he recognised the right of any member of the Corporation to visit the works, but that to do so without notifying him, and to discuss matters with members of the staff, meant undermining his control. The resolution was defeated and Mr. Edgecome's action was endorsed.

**Kingstown: Gas Co.'s Defeat.**—A House of Commons Committee has this week rejected an application by the Dublin & Alliance Gas Consumers' Co. for electric lighting powers in Kingstown, Dalkey, and Blackrock. A rival scheme by the Dublin Southern District Electric Supply Co., promoted by Mr. W. M. Murphy, of the Dublin United Tramways Co., is now under consideration by the Committee. This proposes

only to deal with the district of Kingstown, to which, however, the Council is in opposition, but the feeling of the Committee appears to be that the Company should have the powers, as the Council has not come forward with any definite scheme of its own. A decision has not been reached at the time of our going to press. The Supply Co.'s Order was passed by a House of Commons Committee last session, but was deleted from the Confirmation Bill by the Board of Trade, owing to opposition in the House on the report stage, and the fear of losing the whole of the particular Confirmation Bill, which, of course, contained a number of other orders.

**London: Bermondsey: Black Smoke.**—The Public Health Committee of the Borough Council has written to the Electricity Committee of the Borough Council stating that unless some serious steps are taken to prevent smoke nuisances occurring, it will be compelled to recommend the Council to take proceedings.

**Manchester: Purchase of Trafford Park Co.**—The Manchester Corporation Bill, which includes, among other things, an expenditure of some £200,000, partly in connection with the purchase of the Trafford Power & Light Supply Co., and also in connection with the erection of new power station on the Manchester Ship Canal, is now before a House of Lords Committee. Mr. S. L. Pearce, Chief Electrical Engineer to the Manchester Corporation, spent the best part of Tuesday in the witness chair, and other well-known electrical engineers who are supporting the scheme are Mr. J. F. C. Snell and Mr. C. P. Sparks. There is a good deal of opposition to the proposals, of which further particulars will be given in our next issue.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**R. Waygood & Co.**—An extraordinary general meeting will be held to-morrow to approve a scheme of amalgamation with the Otis Elevator Co. If the amalgamation is sanctioned the name of the new company will be Waygood-Otis, Ltd.

**Chloride Electric Storage Co.**—The directors recommend bringing the ordinary dividend for the year to 10 per cent., plus a bonus of 10 per cent., both free of tax.

**Electrical Apparatus Co.**—A 7 per cent. dividend is being paid on the ordinary shares, £1,000 is placed to reserve, and the formation expenses have been written down by £50 per cent.

**Callender's Cable & Construction Co.**—A 10 per cent. dividend on the ordinary shares for the year, and 5s. per share bonus, has been declared. The directors state in their report that important contracts were entered into last November with the Post Office by which much of the telephone development in the South of England is placed in the Company's hands, and important orders for the cables have been placed. The other cable business is also increasing to a satisfactory extent.

**The Wiremen's Strike in London.**—A Committee meeting of the London Electrical Masters' Association was held on Tuesday, and we are asked to make the following announcement:—The Committee have been making inquiries, and cannot find that any members of the Association are at all inconvenienced by the "so-called strike."—The strike organisers are making every endeavour to broaden the issue of the dispute, so as to affect more employers, but without success. Their latest move was directed against the London District Association of Engineering Employers, who, we understand, have declined to make any concession. We do not think, however, that many of the Electrical Trades Union wiremen are employed by the firms in this Association.

### EVERY INSTALLATION ENGINEER

Should join his Trade Protection Organisation,

THE

**ELECTRICAL CONTRACTORS' ASSOCIATION**

(Incorporated).

Inquiries cordially invited by the Secretary,

L. G. TATE,

## SUMMARY

In a case in the Law Courts on Tuesday, which may have considerable importance as a precedent, judgment was given against an electricity supply undertaking for undue preference in charges for electric power. (Page 266.)

We publish the results of two interesting and important cases in which damages were claimed on account of bad house-wiring. (Page 267.)

HERR RATHENAU, Managing Director of the A.E.G. Co. of Berlin, has stated to an interviewer that his firm has succeeded in producing 50 and 25 c.p. half-watt lamps. (Page 267.)

At a meeting of the newly-formed Association of Supervising Electricians, it was decided that the Association should not take part in trade disputes. (Page 267.)

A DEMONSTRATION of electric vehicles in Birmingham on the occasion of the I.M.E.A. meeting next month is under consideration. (Page 267.)

THE electrical equipment of a granite quarry is described in an illustrated article. (Page 268.)

THE arrangement of negative tramway feeder boosters is discussed in our "Questions and Answers" columns. (Page 269.)

SOME of the Specifications published last week describe improvements in the regulation of cascade motors, duplex telegraphy, automatic telephony and wireless. A patent relating to staff signalling on single line railways expires this week after a life of fourteen years. (Page 270.)

THE London County Council has decided to call in M. Mariage, Directeur Général, Compagnie Générale des Omnibus de Paris, to give advice in connection with the tramways system.—As the result of running tram-cars on Sundays the profits of the Bournemouth Corporation Tramways have increased by £6,000.—An addition to the L.C.C. double trolley line near the Greenwich Observatory has been sanctioned by Parliament.—The proposal of the N.E. Railway to run trolley omnibuses between its Newcastle and Gateshead stations has been rejected by a House of Lords Committee. (Page 271.)

A TOWER as high as the Eiffel tower is to be constructed for a long distance wireless station on the Goldschmidt system, near Brussels. Considerable progress is reported in the Constantinople telephone system. (Page 271.)

A NEW pattern of electric fire, some new glassware, and a large electric sign are illustrated in our Trade Section, which also contains descriptions of various forms of cable junction boxes, an electric cooker with automatic heat regulation, and a sprayer for enamels. (Pages 271 to 274.)

NEW generating plant is required at Stockport, Aylesbury, Woolwich, Leeds, Rangoon, and Walsall; arc lamp carbons are required by the Melbourne City Council; meters at Dublin; electric cranes in Spain; oil break switches in Wellington (N.Z.); and electric lifts at Ashton-under-Lyne. (Page 275.)

THE Manchester Corporation's proposal to purchase the Trafford Power & Light Supply Co., and to extend its area of supply has been rejected in Parliament, but the erection of a new large power station has been sanctioned.—The Bristol electrical contractors are dissatisfied with the present arrangement with the Corporation Electricity Department for wiring consumers' premises.—The Dublin and Alliance Gas Consumers' Co. has met with another defeat in Parliament, this time in connection with the application of the Northumberland clause in the Kingstown electric lighting order.—The Loughborough Gas Committee Chairman has protested against a fixed price system for electric supply as being detrimental to the gas undertaking. (Page 267.)

THE accounts of the B.T.-H. Co. for 1913 show a net profit of £77,044. No dividend is declared, but large sums are placed to depreciation and reserve.—A 6 per cent. dividend is declared by the Electric Construction Co. and by the Craigpark Electric Cable Co.—The Kent Electric Power Co. is able to pay off all arrears of dividend on the 6 per cent. cumulative priority shares. (Page 276.)

Owing to pressure on our space this week, our fortnightly cartoon is postponed.

## ARRANGEMENTS FOR THE WEEK

MONDAY, MAY 18TH.

*Junior Institution of Engineers.*

8 p.m. At Institution of Electrical Engineers, Victoria Embankment. "Static Transformers: Their Design and Application," by F. R. Peters.

THURSDAY, MAY 21ST.

*Illuminating Engineering Society.*

7.30 p.m. Annual General Meeting. "The Nomenclature and Definitions of Photometric Quantities," by A. P. Trotter.

*Institution of Electrical Engineers.*

5 p.m. Annual General Meeting.

SATURDAY, MAY 23RD.

*Association of Mining Electrical Engineers.*

2 p.m. Notts and Derbyshire Branch. Visit to Grassmoor Collieries.

## The London Electrical Engineers.

Headquarters (46 Regent Street, S.W.) open Sat. till noon.  
Rating Exam. for all Cos. from 7 to 10 p.m. every Wednesday.  
Annual course of musketry at Purfleet for all Companies, Saturday, May 16th, and Wednesday, May 20th.  
(To-day) THURSDAY, MAY 14TH, C. Co. FRIDAY, MAY 15TH, D. Co. MONDAY, MAY 18TH, A. Co. TUESDAY, MAY 19TH, B. Co. THURSDAY, MAY 21ST, C. Co. FRIDAY, MAY 22ND, D. Co.

## POWER RATES AND "UNDUE PREFERENCE"

AN important case was decided on Tuesday, with regard to "undue preference" in fixing the charges for electric power supply. Mr. Justice Sargant held that a supply authority has no right to charge different rates for power depending on whether or not the consumer lights his premises by electricity.

Stated briefly, the Judge's construction of the Electric Lighting Act of 1882 is that one consumer may only be charged a higher price than another if it is evident that his supply costs more to the undertaking, from which it follows that to increase or decrease the charges in particular instances merely for the purpose of fighting competition is not allowable. There is reason to believe that the Gas Companies' Protection Association have been supporting the plaintiffs, and that they regard the action as a test case on the question of preferential charging by Electricity Supply Undertakers. Their success may lead to further action in other instances of more important magnitude.

The case in question was an action by the Attorney-General (at the relation of the Long Eaton Gas Co.) against the Long Eaton Urban District Council to restrain the Council from continuing to keep in force a certain tariff of charges for electric supply which, it was alleged, is a breach of Sections 19 and 20 of the Electric Lighting Act of 1882, and constitutes "undue preference." The Council, which works under an Electric Lighting Order granted in 1900, amended its schedules of tariffs as from April 1st, 1910, under which factory lighting was to be charged at 3d. per unit for the first 2,000 units per quarter, with a discount for larger consumptions, whilst for power purposes there was a gradually decreasing scale until at 4,000 units per quarter the charge was 1d. per unit and above 6,000 units ½d. per unit. The supply for power and lighting is given through separate circuits and separate meters. On September 25th, 1911, the Electricity Department issued a circular in which this scale was retained as regards consumers taking current for both power and lighting purposes exclusively, but consumers taking power and no lighting were deprived of the benefit of the ½d. charge above 6,000 units per quarter. This, it was alleged, constitutes an infringement of Sections 19 and 20 of the Electric Lighting Act of 1882, which read as follows:—

19. *Obligation on Undertakers to Supply Electricity.*—Where a supply of electricity is provided in any part of an area for private purposes, then, except in so far as is otherwise provided by the terms of the licence, order, or special Act authorising such supply, every company or person within that part of the area shall, on application, be entitled to a supply on the same terms on which any other company or person in such part of the area is entitled, under similar circumstances, to a corresponding supply.

20. *Charges for Electricity.*—The undertakers shall not, in making any agreements for a supply of electricity, show any undue preference to any local authority, company, or person, but, save as aforesaid, they may make such charges for the supply of electricity as may be agreed upon, not exceeding the limits of price imposed by or in pursuance of the licence, order, or special Act authorising them to supply electricity

Mr. Justice Sargant said that the circular could not be justified unless the combination of power and light cheapened the cost of generation. The Council's case in support of this, however, continued his Lordship, was extremely thin, whilst on the other hand, no technical evidence was called by the Gas Company on this point. Mr. J. F. C. Snell, who gave evidence for the Council, had relied upon the extra business which the tariff would induce in the direction of lighting, but this was inadmissible. The only point in Mr. Snell's evidence which was really relevant was the suggestion that, under the special conditions of Long Eaton, the supply of energy for lighting factories was supplementary to the supply of power, and might improve the load factor. Mr. Snell, however, had had to admit that the lighting load had a worse load factor than the power load. There was, his Lordship concluded, no justification for the differentiation of charges, and the wording of the circular was a strong indication that the reason for issuing it was a desire to oust competition in the supply of lighting. In his opinion there was a breach of Sections 19 and 20 of the Act, and the Gas Co. was entitled to apply for an injunction if necessary. If the Council decided to appeal, an injunction would not be granted pending the appeal. The Council must pay the costs of the action.

The only other case on record of a more or less similar nature to the above was an action successfully brought by the Metropolitan Electric Supply Co., Ltd., against a consumer of the name of Ginder in 1901. Ginder had agreed to take all his supply from the company for five years at 4½d. per unit, but found that the company subsequently supplied another consumer at 4d. per unit, and held that he was no longer bound by the agreement. The more-favoured consumer had a good day-load, however. The interpretation by Justice Buckley of the phrase "similar circumstances" in the above Clause 19 was as follows (we quote from Shirees Will's "Law of Electric Lighting") :—

The phrase "similar circumstances" in Section 19 embraced amount of energy consumed, the expense of supplying it and getting payment, uniformity of demand and the time when the energy was required, and unless all the circumstances were similar, agreements might lawfully be made for different terms and at different rates.

The above definition will be useful as a guide to supply station engineers and managers as to the extent to which they may vary their charges to different consumers.

**The Organisation of Empire Trade.**—This is the title of an excellent article by Mr. Hugo Hirst, Chairman of the General Electric Co., which appears in the first number of the *Britannic Review*, just issued. Mr. Hirst urges that practical steps should be taken to consolidate and co-ordinate the rules governing the great trading communities within the British Empire. The appointment of Trade Commissioners he recognises had been a step in the right direction, but this had been limited to self-governing dominions, and nothing has been done in connection with the Crown Colonies. As instances of the present state of affairs, Mr. Hirst mentions that 32 Crown Colonies and Native States have separate patent laws or ordinances, and that Australia, New Zealand, Canada, and Newfoundland have all different patent laws. It costs a British inventor £500 to £600 to get a patent in force throughout the Empire, while a patent may be made valid throughout the United States for about £20. The establishment of a common basis for trade statistics, a uniform classification of dutiable goods, and reform of the methods of taxing commercial travellers are among the suggestions made in the article.

**The Toronto Hydro-Electric System.**—The third annual report of the Toronto Electric Commissioner, under whose control is the distribution system in Toronto, which is supplied from Niagara by the Hydro-Electric Power Commission of Ontario, refers to the appointment of Mr. H. H. Couzens last year as General Manager, under a three years' agreement, and mentions that the former Acting General Manager and several of his subordinates had been peremptorily dismissed, and this was followed by a strike, which was afterwards settled by arbitration. Notwithstanding these difficulties, there has been a net profit of \$34,575, after paying interest, depreciation, sinking fund, &c. It is pointed out that if the undertaking were a company with share capital, the surplus would be equivalent to a 7½ per cent. dividend. During the year the peak load has increased by 31 per cent., the consumers, as measured by number of meters, by 80 per cent., and the street lamps by 15 per cent. The cost of current has been reduced considerably, and the load factor has been raised from 59.5 to 70.4 per cent. It has been decided to install a steam reserve plant at a cost of \$1,000,000.

## TWO LAWSUITS ON WIRING

JUDGMENT was given on Friday in an interesting case, which had lasted three days, on the question of a claim for breach of contract in connection with the wiring of Mrs. Irene Osgood's house, Guilsborough Hall, Northampton. In February, 1904, Mr. Leo Sunderland's offer to wire the house was accepted, and it was arranged that concealed work should either be in American whitewood casing or in brazed steel tubing. The work was completed a few months later and duly paid for, and down to 1909 Mr. Sunderland, by arrangement with his customer, sent down to inspect it every six months. In December, 1909, a hot-water installation was put in the house, and in 1912 some structural alterations were made inside the house, as a result of which some of the wiring was exposed. This revealed, it was said, that some of the wiring was not protected by tubing or casing, and it was alleged that a subsequent examination had revealed that under the floors the tubing or casing only covered the wires for a short distance under the screwed boards, where it would be liable to be uncovered and seen, and that elsewhere the wire was unprotected. This, it was claimed, amounted to fraudulent misrepresentation as to the nature of the work done, and that therefore, although the period between the acceptance of the installation and the present claim exceeded six years, the Statute of Limitations would not apply. It was not suggested that Mr. Sunderland was personally aware of the bad work when it was put in, but it was contended that he should nevertheless be held responsible for it. It was acknowledged on both sides that bad tests had been obtained on the installation due to dampness, and eventually the whole installation was rewired by another firm. For Mr. Sunderland it was contended that the wiring had been pulled about during the putting down of the hot-water installation, but Mr. Justice Bailhache decided "with much reluctance" that the work had been badly done originally, and that steps had been taken to conceal it. After reviewing the case, in connection with the application of the Statute of Limitations, however, he gave judgment in favour of Mr. Sunderland, with costs, except as to issues of facts.

Although relating to house-wiring, this case differs from that of the War Office against Messrs. Kirkland & Capper and Mr. Woodd, judgment on which has been given since the publication of our report of the case in our issue of April 23rd. It will be remembered that the War Office claimed damages from the architect, Mr. Woodd, and the consulting electrical engineers, Kirkland & Capper, for negligence in permitting lead-covered wire to be placed under plaster, without other protection, in the wiring of the Royal Army Medical College and Laboratories at Millbank. In giving judgment, Mr. Justice A. T. Lawrence held the architect, as well as the consulting engineers, responsible, for he said there was an entire want of co-ordination between them. If it had been thought that the "Frazzi" blocks used in the building could not be covered, it would have been easy to have specified a thicker coat of plaster to take the tubing; moreover, he said, it had been demonstrated in Court that the blocks could have been chased without difficulty before erection. The installation was completed in May, 1907, and the free maintenance period expired in May, 1908. Even during this period, however, there had been trouble with the installation, and finally in July, 1909, twenty-three out of eighty-three circuits in the College were defective and the number had risen to thirty by January, 1910, when the defects were located to the actual wiring, and not in fittings or switches. The bare lead-covered wires under plaster, he held, did not comply with the specification that they should be accessible. Further, he was satisfied that the supervision of the work had been inefficient; the bonding at the connector boxes was bad, the wires showed signs of having been bent too sharply, wires were run against edges of brickwork without any protection, flexes were knotted at the ceiling roses, and there was no attempt to provide any protection against nails or any plan to show where the wires were. He did not accept the contention that the faults had been caused by the War Office employees putting in too heavy fuses. Finally, the judge commented unfavourably on the fact that the fee of 5 per cent. of the value of the electrical work which was to be paid by the War Office to Messrs. Kirkland & Capper was shared with Mr. Woodd in the proportion of 4 per cent. to Kirkland & Capper and 1 per cent. to Woodd, a fact which was unknown to the War Office or its advisors until after the present action had been brought.

In the College, as has already been said, thirty out of

eighty-three circuits were defective; in the laboratories, seven out of seventy-four. The damages awarded against the defendants by the Judge are limited to the cost of reinstating these circuits in an approved method, and if the cost of these is not agreed between the parties, the matter is to be referred to an official referee for decision. Judgment was given for the plaintiff for the amount so agreed against both sets of defendants, and with costs.

## 25 C.P. HALF-WATT LAMPS!

THE *Berliner Tageblatt* last week published an "interview" with Geheimrat Emil Rathenau, Managing Director of the A.E.G. Co., of Berlin, in which he stated definitely that his Company had succeeded in producing not only 200 c.p. lamps, but also lamps of 50 and 25 c.p. consuming only half a watt per c.p.

In the course of the interview, Herr Rathenau referred also to the growing tendency for amalgamation and centralisation of power supply. Herr Rathenau has always been a strong advocate and a strenuous fighter for private enterprise; it is significant that he expressed the opinion that the smaller undertakings will not be able any longer to withstand the strong movement for amalgamation, particularly in view of the coming reduction of the lighting load consequent upon the introduction of the new lamp. They will, he said, find it necessary to amalgamate and take current either from large central stations owned jointly by the small undertakings, or from one of the large State power stations now under construction mainly for railway supply. One such station has already contracted to supply 30 million kw.-hours yearly to such local undertakings. On the other hand, a State monopolisation of electricity supply for the whole of Germany, Herr Rathenau continued, is hardly probable, particularly as the separate States of Bavaria and Baden have already commenced to establish electricity supply networks of their own in connection with the utilisation of the State water-power rights, but such monopoly is quite conceivable for the State of Prussia. Such monopolisation would enormously facilitate and cheapen the long-distance transmission of electrical energy, especially if coupled with compulsory wayleaves for overhead lines and cable routes.

## THE ASSOCIATION OF SUPERVISING ELECTRICIANS

A GENERAL meeting of this Association was held at St. Bride's Institute, E.C., last Thursday. It was decided that the headquarters should be at St. Bride's Institute, and that the membership should be confined to foremen, supervising engineers, and managers in the electrical contracting trades. It is intended to admit only men of undoubted qualifications. The subscription is 10s. per annum, payable 2s. 6d. quarterly in advance, with an entrance fee of 5s. for London members and 5s. for country members. Honorary members are eligible at a subscription of not less than one guinea per annum. It was resolved that a Benevolent Fund should be formed, and honorary members' subscriptions and all special donations should be placed to a reserve fund available for the benefit of members requiring assistance. It was also decided to keep a register of vacant situations, and to insert advertisements in trade journals for members out of employment. A resolution was unanimously passed that the Association should not take part in any trade disputes. Particulars of the Association may be obtained from the Honorary Secretary, 14 Pulborough Road, Southfields, S.W. The objects of the Association are:—To assist members in obtaining information of situations; to form a technical library; to form a Benevolent Fund; to hold lectures and to arrange visits to works; to foster the apprentice system; to extend the attendance of electrical workers to evening schools; to arrange reading of Papers on electrical subjects, and social gatherings.

**Electric Vehicles.**—Mr. E. W. Curtis, jun., Vice-President of the General Vehicle Co., of Long Island, U.S.A., has been elected a member of the Electric Vehicle Committee during his stay in England. Mr. J. W. Beauchamp (West-Ham Corporation Electric Supply) and Mr. K. Bowen (director of the Cedex Electric Traction Co., Ltd.), have also been invited to become members. A demonstration of electric vehicles in Birmingham on the occasion of the Incorporated Municipal Electrical Association's Convention in June is under consideration. With regard to the standard charging plug, a design for the earthing contact has been provisionally decided on; and as to maximum carrying capacity, heating tests are to be made by the Acting Hon. Secretary of the Technical Sub Committee, Mr. J. Christie. This Sub-Committee has been considering the possibility of standardising battery trays, but there appear to be difficulties in the way, and they decided to obtain the views of battery makers as to the feasibility of standardising the height and width of lead battery plates as a commencement.

## ELECTRICITY AT A GRANITE QUARRY

**I**N stone-working plants the machines are generally scattered over a considerable area. The conditions are in most cases unfavourable to the efficient operation of steam engines, and the use of electricity possesses special advantages in its low transmission losses, high efficiency at all loads, and high overload capacity of the motors.

When the plant is of very large size, or a central station supply is not available, it may sometimes be advisable to instal a steam or oil-driven generator in a central position

FIG. 1.—100-H.P. MOTOR DRIVING HAULAGE GEAR.

on the premises, but in the majority of cases it will be found more economical to purchase power from a supply station.

A good example of an up-to-date stone-working plant is the Griff Granite Quarry, near Nuneaton, a description of the electrical equipment of which has been sent us by the British Thomson-Houston Co., Ltd. The stone from this quarry is used chiefly for setts, road metalling, concrete making, &c. The granite is freed by blasting; air-driven rock drills are employed, fed from an electric motor-driven compressor situated in a central position near the crushing mill, through a piping system serving convenient points in the workings. The large masses of granite detached by the blasting operations are first broken up by hand to roughly the size required

FIG. 2.—14-H.P. ELECTRIC CAPSTAN WITH CRUSHING MILL IN BACKGROUND.

for setts, and the small blocks thus obtained are then transferred either to the crushing mill, where they are broken up to a size suitable for road metal, &c., or to sheds, where they are cut to size for setts. The rough material is conveyed from the workings to the mill, &c., in trucks which are hauled by a 100-h.p. B.T.-H. electric motor situated in a haulage house at the highest point of the property, the empty trucks being returned to the workings by gravity. The finished product is despatched either by canal or by rail, and for handling the railway trucks in the quarry yard two electric capstans are installed. These have the ropes permanently attached to the drum, and are operated by B.T.-H. 14-B.H.P.

electric motors, which, with their controllers, are placed below the ground under the capstan head. The controller is operated by a lever which also operates a clutch, by means of which the drum can be disconnected from the motor when the trucks are running down the incline.

A considerable amount of water has to be dealt with, owing to underground springs. For the removal of this, two pumping sets have been installed, and an additional set is ready to be erected when it becomes necessary. Each of these sets consists of a Pulsometer Engineering Co.'s centrifugal pump direct-coupled to a B.T.-H. type motor rated at 9 to 29 h.p., with a speed variation of 1,150 to 1,900 r.p.m. One of these sets, situated in the northwest part of the workings, is required to operate for three to six hours per day, the length of time varying with the state of the weather. This is due to the fact that in wet weather a considerable quantity of surface water has to be dealt with, in addition to the spring water, which is fairly constant in quantity. This set can be arranged to deliver water to a tank situated alongside the

FIG. 3.—9 TO 29-H.P. MOTOR RUNNING AT 1,150 TO 1,900 R.P.M. DRIVING CENTRIFUGAL PUMP.

haulage house, or alternatively to discharge it into the canal, the heads against which the pump is working being 120 ft. and 60 ft. respectively in the two cases. The second set is at present required to deal with surface water only, as no springs have yet been struck in the part of the quarry where it is installed. All the motors used in this quarry are operated from a 420-volt D.C. supply obtained from the Nuneaton Electric Supply Co., the power being brought to the quarry by an overhead transmission line about two miles in length.

The installation here described is used entirely for the rougher part of stone-working, but, as an example of the use of electricity for stone cutting, as distinct from quarrying, we may mention the works of Messrs. Tomes, Good & Co., Ltd., of Fulham, where B.T.-H. two-phase slip-ring-type induction motors are used to drive sawing frames for cutting rough blocks of marble into slabs of suitable sizes for building purposes, monumental works, &c.

**Frequency Changing by Static Transformers.**—After the reading of his Paper at the meeting of the Birmingham Local Section of the Institution of Electrical Engineers on April 29th (see *ELECTRICAL ENGINEERING*, April 30th, page 238), Mr. A. M. Taylor showed experimentally that the apparatus was reversible and obtained a 25-cycle current from a 75-cycle supply. He suggested that this arrangement might be useful for the supply of power for electric furnaces, and if the power factor difficulty could be satisfactorily overcome for electric railways, or any application where close voltage regulation was not necessary. He also went into the question of power factor of the ordinary apparatus, which is very low, being only of the order of 0.2, and argued at some length that in many cases it would pay to instal phase advancers in conjunction with the system.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,391.

A .20-h.p. shunt-wound motor running at 510 r.p.m. has been put in to drive the main shafting of a machine shop at 120 r.p.m. The rated full load current is 75.5 amperes at 220 watts. When the planing machine is in action this current is not exceeded on the cutting stroke, but rises to 120 amperes on the return stroke. Will some reader suggest a remedy? Would it be practicable to alter the gear ratio between the motor and shafting, and to increase the speed of the motor by weakening its field?—"ELECTRIC MOTOR DRIVE."

(Replies must be received not later than first post, Thursday, May 21st.)

### ANSWERS TO No. 1,389.

In a tramway station using three negative boosters connected at three different points of a common continuous rail return, and with no other connection to the rail, the station being some 2,000 yards from the tram track, the earth plates are fixed at the station; does this violate the B.O.T. Rules? If one of the boosters was connected with the wrong polarity, instead of sucking, what would happen? If one of the boosters broke down would it be advisable to cut it out and short across, bearing in mind the long length of return cable, over 2,000 yards,

Fig. 1.

and that the negative bar is earthed at the station? Is there any necessity to fit any protective device to protect the booster in the event of the circuit-breaker on the motor circuit acting and cutting out the motor, bearing in mind that the boosters are plain shunt wound and separately excited off the traction bus-bars? On what basis would you regulate the pressures of the three boosters? The ohmic resistance of the negative returns are all about equal, and are connected to one continuous rail.—"ELECTROLYSIS."

The first award (10s.) is given to "E. B. P.," who writes as follows:—

Section No. 5 (e) of the B.O.T. regulations for tramways and light railways states that:—

"When the generator is at a considerable distance from the tramway, the uninsulated return" (i.e., the rails) "shall be connected to the negative terminal of the generator by means of one or more insulated return conductors, and the generator shall have no other connection with earth; and in such case the end of each insulated return connected with the uninsulated return shall be connected also through a current indicator to two earth-plate connections," &c.

As in this case the generating station is over 2,000 yds.

from the tramway, it would seem that this regulation is not complied with by earthing the negative bus-bar at the station, and that the only connection to earth should be at the rail end of the negative feeders, where, also, the necessary earth plates, current indicators, &c., should be connected, the station ends of the feeders and the negative bus-bars being insulated. But apart from this, the present arrangement is not good. Reference to Fig. 1 will show that there is a circuit from the boosters, to the negative bus-bar and earth-plates, through the earth to the rails, and so back along the negative feeders to the boosters, and as the latter are separately excited it will be very difficult to prevent them sending a current on their own account through this circuit, in addition to whatever current may be returning from the rails; this being a waste of energy, and involving serious danger to water-pipes, &c., from electrolysis. If the system were only earthed at the rail, this could not occur. Moreover, if they were constructed as series machines instead of shunt, and the field excited by the current flowing in the corresponding positive feeder, the boost would be approximately proportional to the load, and there would be very little current in the local earth circuit, even if both ends of the feeders were earthed. It may be mentioned that this series arrangement is the more usual.

It is a little difficult to see what is the object of the arrangement of boosters in the present example. The three negative feeders appear to be all of about the same length, whereas negative boosters are usually installed to keep down the rail drop by inducing the current from a distant part of the tramway to return by a long negative feeder, instead of all returning by the rails to a shorter one. Consequently, no basis can be suggested for regulation of the booster voltage at all, and, for all the use they are, they might as well be scrapped. But if there is any difficulty in getting the current to distribute itself properly between the three feeders, either due to large differences in length or any other cause, then the boosters could be used to correct the same. In that case they ought to be regulated so as to ensure that the current returning by each negative feeder shall be about the same as that in the corresponding positives. As previously mentioned, series-wound machines would ensure this automatically.

If one of the boosters were connected up with the wrong polarity, if its field were weak, the current returning *via* that feeder would be reduced, while if the field were strengthened sufficiently, the direction of the current would be reversed, and it would flow from the booster to the rail, returning by the other negative feeders to the negative bus-bar, and thence back to the faulty booster. The current leaking from the rail to the station earth plates would also be increased.

In case of a booster breaking down it would be well to cut it out and short across in order to reduce the resistance in that circuit as much as possible.

If the motor circuit-breaker were to operate, the booster would be likely to race away in the reverse direction, consequently it ought to be provided with an automatic switch to cut it out, and preferably, short-circuit it. This switch could be operated by the motor circuit-breaker, or, better, by a centrifugal device. As the rotation of the machine would be reversed, an alternative method of protection would be a ratchet clutch on the shaft to prevent the reversal occurring.

No second award has been made.

### ANSWER TO CORRESPONDENT

FLASH.—We do not think that the breakage of the filament can be attributed to the short circuit in the lamp holder.

**The Batti-Wallahs Society.**—The following is a list of provisional dates for the coming season's programme: Up-river trip, June 27th; barge trip, July 31st to August 10th; ship visit, during September; smoking concert, October 2nd, 1914, and January 8th, 1915; informal evenings, October 21st, November 18th, December 16th, 1914, and February 3rd, March 31st, and April 21st, 1915. Annual dinner, February 27th, 1915, and annual general meeting, March 8th, 1915. Secretaries of other Societies who may have settled on any dates which clash with the above are invited to communicate with the Hon. Secretary, Mr. F. Pooley, 25 Victoria Street, S.W. We hear that for the up-river trip on June 27th the *Royal Thames* has been chartered, which will accommodate 150 Batti-Wallahs, ladies, and friends.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published May 7th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

8,968/13. **Arc Lamps.** T. F. BRYEN, E. A. GOLDING, and H. J. PEARCE. This invention applies to lamps used for projection apparatus, where it is desirable to keep the arc in the same horizontal plane whilst the carbons are being consumed. A flame arc is used, and the carbons are inclined at equal angles at each side of the optical axis of the apparatus and are fed in the usual manner, the feed mechanism being adapted to suit. One figure.

9,260/13. **Cascade Motors.** L. J. HUNT and SANDYCROFT, LTD. The rotor windings are connected to six slip-rings instead of to three as at present. By inserting appropriate resistances between the various slip rings, local currents in the windings are obviated. The power factor is thus kept up, at speeds much below the normal. Five figures.

9,261/13. **Starting of Synchronous Motors.** L. J. HUNT and SANDYCROFT, LTD. The rotor windings are suitably connected to the slip-rings, and extra coils are provided in the stator windings, for direct current excitation. An exciter is direct-coupled to the shaft, and supplies current to these extra coils. In starting, resistances are inserted between the slip rings, and the machine starts as an ordinary induction motor, and will tend to speed up beyond cascade synchronism. The D.C. field prevents this, and when this field is strengthened, and the slip-rings open-circuited, the machine runs as a synchronous motor at cascade speed. Four figures.

9,893/13. **Electrically-operated Rock Drills.** T. F. WALL. Two solenoids are used, one for the forward stroke and one for the return stroke. They are connected in series and are excited alternately, the alternate connections being controlled by the movements of the plungers. Either A.C. or D.C. excitation may be used. An automatic rotary motion is imparted to the drill during its working stroke. Three figures.

14,487/13. **Automatic Telephone Systems.** SIEMENS & HALSKE AKT.-GES. An improved system of inter-connections whereby in the case of subscribers belonging to the same exchange, the junction lines leading to the main exchange are only used during the connecting up of the calling and called lines. Hence fewer junction lines between exchanges are needed. One figure.

18,663/13. **H.T. Transformers with High Reactance.** B.T.-H. (G.E. Co., U.S.A.). In place of the laminated iron strips before used, a flat strip is wound in a spiral, directly over the secondary winding of the transformer. This device is found to give a straight line reactance from no load to full load, whilst at the same time, great mechanical rigidity is obtained. Two figures.

24,347/13. **Preparation of Aluminium Nitride.** SOC. GÉNÉRALE DES NITRURES. A mixture of alumina and carbon is heated in an atmosphere of nitrogen in an electric furnace. The materials themselves serve as the heating resistances. The furnace is divided into a number of sections, and electrodes, in the form of metal joint rings, are situated between the sections. The furnace revolves during operation. The heating effect in each section depends upon the length of the latter and the voltage between the electrodes at each end, and can be varied in different parts of the furnace, as required. Two figures.

27,175/13. **Radio-telegraph Stations.** MELLERSH JACKSON (Signal Ges.). Method of improved wireless communication with airships. In place of stations using ordinary long waves, special short-wave land stations must be used, giving waves of the same order as the apparatus carried by airships. The antenna structure must be raised above the ground a distance which is a multiple of its own height. The land station may be either on the ground level or supported on a platform. Two figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** WEISS, 24,243/13.

**Distributing Systems, Cables and Wires, &c.:** HAWORTH [Transmission gear control] 9,996/13; SIEMENS BROS. (Siemens Schuckertwerke [Flexible connections] 29,003/13).

**Dynamos, Motors, and Transformers:** SANCHEZ and BARADAT [Generator for automobiles] 22,228/13; SIEMENS BROS. [Ventilation of electric machinery] 29,203/13; SIEMENS SCHUCKERTWERKE Ges. [Cooling arrangements for rotors] 5,828/14.

**Incandescent Lamps:** VOIGTLANDER [Manufacture of tungsten] 6,911/13.

**Instruments and Meters:** XENAKY and GILMAN [Generator efficiency indicator] 17,066/13; B.T.-H. (G.E. Co., U.S.A.) [Electrolytic meters] 2,850/14.

**Storage Batteries:** DE MELLO [Batteries] 24,471/13.

**Switchgear, Fuses and Fittings:** PRIM and ROPER [Thermostats for electric circuits] 9,140/13; B.T.-H. (G.E. Co., U.S.A.) [Switches] 9,384/13; SOC. D'ELECTRICITÉ MORS. [Railway switches] 22,127/13; COLAS and SOC. D'ELECTRICITÉ "NILMELLOR" [Electrical contacts] 23,754/13.

**Telephony and Telegraphy:** HULFISH [Telephony] 4,071/13; FURNIVAL [Automatic telephones] 9,205/13; AUTOMATIC TELEPHONE MFG. Co. (Automatic Electric Co.) [Telephone systems] 9,593/13; JUDD, DAVIES, and EASTERN TELEGRAPH Co. [Telegraphy] 9,768/13; SMITH [Telephone mouthpiece cover] 18,902/13; SORENSEN [Brush for high-frequency apparatus] 22,176/13; GRAHAM [Telephone systems] 26,287/13; VOIGTSBERGER and WEST [Transcribing apparatus for telegraphs] 83/14; HASTINGS [Impulse transmitter for telephone systems] 4,082/14.

**Traction:** PARTINGTON [Locomotive signalling] 22,386/13; PRIOR [Lighting for road vehicles] 24,898/13.

**Miscellaneous:** IRVING and O'DONNELL [Electrically-controlled valves] 11,623/13; SCOTT [Engine-starters] 14,742/13; SIEMENS BROS. [Paper-feeding device] 17,125/13; FR. HESSER MASCHINEN-FABRIK AKT.-GES. [Releasing device for packing-machines] 3,004/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, Cables and Wires:** CONCORDIA ELECTRIZITÄS Ges. [Wiring installations] 8,982/14.

**Dynamos, Motors and Transformers:** SIEMENS SCHUCKERTWERKE Ges. [Synchronizing rotary and cascade converters] 7,684/14, 9,225/14; SOC. ANON. DES AUTOMOBILES ET CYCLES PUGOT [Brushes] 9,231/14; YARDLEY [Dynamo-electric machine] 9,280/14.

**Electrometallurgy and Electrochemistry:** Ges. FÜR ELECTRO OSMOSE [Diaphragm for electro-chemical purposes] 9,265/14.

**Ignition:** KELLER-DORIAN [Magneto] 8,931/14; TISMER [Spark-plugs] 9,444/14.

**Incandescent Lamps:** KREMENEZKY [Filament supports] 19,838/13; SCHAEFER [Holders] 8,806/14.

**Instruments and Meters:** BECKMANN [Eddy current speed indicators] 3,021/14.

**Switchgear, Fuses and Fittings:** DIRKS [Control of lift switches] 9,289/14.

**Telegraphy and Telephony:** SIEMENS & HALSKE AKT.-GES. [Automatic telephone systems] 459/14.

**Miscellaneous:** KRAMER [Drive for talking machines] 7,566/14.

### Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

8,998 of May 15th, 1900. **Railway Signalling.** E. W. SMITH. A system of staff signalling for use on single-line railways. The staffs are contained in holders at each end of the section, and it is rendered impossible for the engine-driver to remove a staff from its holder until the correct signal has been sent by the operator at the other end. This is accomplished by an arrangement of interlocked levers, controlled by an electro-magnet. When the magnet coils are energised, the armature is attracted and unlocks the levers, thereby allowing one staff to be removed from the holder. A bell, preferably of the polarised type, is used for signalling, and the current for operating both the magnet coils and bell is obtained from a magneto generator which gives both direct and alternating current. Seven figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** M. FORTNY [Arc lamp with motor-driven feed mechanism] 1,410/06; H. E. MARL [Arc lamps with inclined, self-cleaning electrodes] 1,596/08; P. HANISCHE [Circuit breaking device for arc lamps] 1,813/09.

**Dynamos, Motors, and Transformers:** O. DE FARIA [Electrolytic rectifier] 1,456/07.

**Storage Batteries:** J. B. MILLS (T. A. Edison) [Machine for forming accumulator plates] 1,929/06.

**Telephony and Telegraphy:** A. J. BOULT (International Telechronometer Co.) [Telephone system with automatic call recorder] 1,548/09.

**Traction:** C. J. SPENCER [Railway signalling. Signal lamp circuits closed and opened by the train entering and leaving each section] 1,695/06.

**Miscellaneous:** J. S. STEVENS and H. MAJOR [Lift control. A device for cutting out resistance from motor circuit when lift starts] 1,401/01; OTIS ELEVATOR Co. [Pneumatic control of lift motors] 1,548/02; WATTS [Advertising device] 1,765/09.

## ELECTRIC TRACTION NOTES

Monsieur A. Mariage, General Manager of the Compagnie Générale des Omnibus de Paris, has been appointed to assist the Council with regard to schemes which have been prepared for the consolidation and linking-up of the Council's tramways system at an inclusive fee of £250, plus £75 for an assistant to act as interpreter.

The Bristol Tramways Committee, in view of the decision of the House of Lords Committee, given in our last issue, has decided to recommend the Council to purchase the whole of the Bristol Tramways & Carriage Co.'s undertaking.

The Hastings & District Electric Tramways Co. has now six Tilling-Stevens petrol-electric tramcars on the old route upon which the Dolter surface-contact system was used, and a further eleven are on order.

The financial result of the past year's working on the Bournemouth Corporation Electric Tramways are extremely interesting, owing to the influence upon them of the running of the tramcars on Sundays. This policy had been defeated in the Council for many years in succession, but last year (the first in which the cars had been run on Sundays) shows that £6,000 of the profit is due to this fact. There was a net profit of £13,167 for the year, as against £10,320 in the previous twelve months.

The proposal of the North Eastern Railway Co. to run trolley-omnibuses between its Newcastle and Gateshead stations has been rejected by a House of Lords Committee. The scheme was strongly opposed by the Newcastle-on-Tyne Corporation, who offered to promote a scheme to carry trams across the Gateshead Bridge next session. The scheme, however, was rejected without any liability on the Corporation to carry out its suggestion.

The Potteries Electric Traction Co. placed a suggestion before the Stoke-on-Trent Borough Council that the right of the Corporation to purchase the Company's undertaking should be synchronised so that one date should apply for the purchase of the whole undertaking, and that this should be December 31st, 1940. In return for this extension the Company offers to pay certain wayleaves to the Corporation, and to carry out a number of improvements estimated to cost £35,000. These terms are practically agreed, and the Tramways Committee recommends their acceptance.

A House of Commons Committee has sanctioned the construction by the L.C.C. of 1½ miles tramway along Eltham Road, which is to be constructed on the double-trolley system. The L.C.C. has experienced no trouble with the existing double-trolley line which was constructed to prevent interference with Greenwich Observatory.

TELEPHONY AND TELEGRAPHY  
(INCLUDING WIRELESS)

A report issued by the Constantinople Telephone Co. to December 31st states that the three principal exchanges at Stamboul, Pera, and Kadikuey are now in operation, and extra plant has been necessitated by the developments at the Pera exchange. Orders for 4,605 telephone stations are in hand, and submarine cables have been laid between Golden Horn and Bosphorus. The capital expenditure at December 31st amounted to £302,446.

Gratifying results are reported from a new automatic exchange installed by the United River Plate Telephone Co. at Cordoba. A second exchange of the same type, viz., the Strowger, is on order for Rosario.

An international congress of telegraph and telephone engineers is to be held in Berne in September. Among the subjects to be discussed are the protection of telephone and telegraph lines from electric power currents, long-distance land and submarine telegraphy, and automatic telephone exchange working.

In the course of a recent interview, Prof. E. W. Marchant (Liverpool), who has recently returned from a wireless conference in Brussels, announced that Dr. Goldschmidt intends to erect shortly at his wireless laboratory at Laeken an aerial 333 metres in height, or as high as the Eiffel Tower. The present tower is 70 metres in height. The wires will cover an area more than a quarter of a mile across. The Belgian Government hope to get into communication with the Congo from the station.

The report of the Great Northern Telegraph Co. (Denmark) records slightly lower traffic and slightly higher expenses than last year, although the usual dividend of 20 per cent. for the year is possible. An increase in cable interruptions in the Far East is attributed to the more common use of trawlers in Chinese and Japanese waters. The West Coast of America Telegraph Co. also reports trouble with interruption. Their various sections were interrupted for an aggregate of 114 days, principally owing to earthquakes.

At the meeting of the Anglo-American Telegraph Co. last week it was stated that a decision has been come to to keep about 335 miles of new cable on hand permanently for general purposes. The Company is about to purchase this quantity at a cost of £50,000.

On the 8th inst. landline communication with Siam *via* Moulmein was normal again.—There has been some derangement of lines in the British Isles recently, but repairs have been effected.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 275. —

## CATALOGUES, PAMPHLETS, &amp;c., RECEIVED

**CUTTING-OFF MACHINES.**—A rotary cutting-off machine for bars, tubes, &c., is described in a revised edition of a catalogue from Charles Taylor, Ltd. (Bartholomew Street, Birmingham). These machines were first introduced in October, 1912, and 55 have been sold since. They are solidly made, and rapid in action. The catalogue deals with the 3-in. size of machine, but machines for work up to 1½ and 8 in. respectively will shortly be introduced.

**GOVERNORS.**—A leaflet from Percy Pitman (3 Willcott Road, Acton, W.) deals with a new pattern of hydraulic governor for controlling water turbines, Pelton wheels, &c. The leading features of these were described in a Paper by Mr. Pitman recently published in the proceedings of the Institution of Mechanical Engineers.

**ALLOYS.**—Miralite, Ltd. (52 Gracechurch Street, E.C.), have sent us a booklet describing the features of a new untarnishable uncorrodible aluminium alloy, which can be cast, rolled, spun or drawn, and has a tensile strength from 12-14 tons per square inch.

**ENGINEERING PLANT.**—A booklet from E. G. Appleby & Co. (12 The Broadway, Westminster, S.W.) calls attention to some of their specialities, including gas-producer plant, lift magnets, cranes, and transporters, &c.

**DRY CELLS.**—A leaflet from The Edison & Swan United Electric Light Co., Ltd., gives particulars of a new form of the "E.C.C." dry cell for which the company hold the sole selling rights for the United Kingdom.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**CABLES AND WIRES.**—Prices of 600 megohm grade I. R. cables, bell wires and flexibles are contained in a special nett list from Ralph H. Haylock & Son, 63 Queen Victoria Street, E.C.

**EQUIPOISE TELEPHONE ARM.**—We have received from Messrs. the Sterling Telephone & Electric Co. (210-212 Tottenham Court Road, London, W.) a pamphlet describing the "Equipoise" telephone arm, which can be fixed to the desk or wall and swivelled into any position most convenient when required.

## "MAGNET" ELECTRIC FIRES

THE Heating Department of the General Electric Co., Ltd., has recently evolved two types of heaters known as "Magnet" electric fires, in which the element is run at a most pleasing glowing temperature. These electric fires are made in numerous designs. In one form, the Panel type, a special non-oxidising high-resistance wire is wound in a helix and arranged in specially-designed fire-resisting insulators. These are curved from top to bottom, as may be seen from Fig. 1, and the terminals of each section are arranged at the bottom corners. The fire-resisting insulator is grooved from top to bottom, and the wire helix lies in these grooves, starting from its point of entry up to the top, through a hole for anchoring purposes, down the next groove through a similar hole at the bottom, and up the next groove through another hole, and down to the other terminal. The wire helix is further anchored by specially-designed pegs passing through holes in the insulator arranged for the purpose. Thus, the spacing of the individual turns of the helix is maintained constant. Each element is designed for 500 watts, and the standard fires are arranged for 1,500 or 2,000 watts. Two switches are provided to give different degrees of heat. These

FIG. 1.—PANEL TYPE.

FIG. 2.—ROD TYPE.

heaters, which are particularly light in weight, are finished in iron, copper, or brass in the Modern, Adam, Sheraton, and Georgian styles.

Another form is the rod type, shown in Fig. 2. Each heating element consists of a fire-resisting insulator rod, reinforced by a central steel rod, and having fine grooves arranged helically on its surface. These grooves accommodate a special non-oxidising metal wire. At the end of each rod connection is made by the end turns of the wire to a specially large surface nickel terminal strip, so that this runs perfectly cool. Each rod is designed for a power consumption of 500 watts, and the terminal fits into vertical metal strips of substantial size at the side. The standard sizes are for 1,500, 2,000, and 3,000 watts. Behind the rods, at a suitable distance, is a curved aluminium reflector. We understand that the General Electric Co., Ltd., is inaugurating a novel scheme whereby those interested in the supply of heaters on a large scale for sale, hire, or hire-purchase, will be able to extend considerably their activities, and they are recommended to apply to the Heating Department of the General Electric Co., Ltd., at 67 Queen Victoria Street, E.C., for particulars, as well as for information and advice, on all heating problems.

**Cinematograph Transformers.**—A special series of transformers for use in stepping down the supply voltage to a value suitable for cinematograph arc lamps where alternating current is available, has been standardised by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.). Such an arrangement is of course much cheaper than a motor-generator, and is far more efficient than the use of resistances.

**Smart Emergency Work.**—The British Thomson-Houston Co., Ltd. (Rugby), send us a translation of an extract from the *Jewish Express* describing a breakdown to two motors used for driving the machines on which that journal is printed. Application was immediately made to the Stepney Borough Council's Electricity Department, and within three hours a new nine h.p. B.T.-H. motor was installed, so that printing could be continued without interruption.

## ELECTRIC SIGNS

A GREAT variety of different forms of electric signs suitable for all sorts of positions is made by Simplex Conduits, Ltd. (Garrison Lane, Birmingham). A new one

AN EFFECTIVE ELECTRIC SIGN IN BIRMINGHAM.

just erected in Birmingham is illustrated here. It is a three-sided sign, over 25 ft. high, each letter measuring 24 in., alternate spaces being arranged as doors for changing lamps or inspection purposes. Twenty-four 50-c.p. lamps are used for lighting, the sign being legible at a great distance.

## NEW VELURIA GLASSWARE

WE are informed by the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), that the demand for Veluria direct-lighting reflectors and shades has increased so rapidly that they have thought the time opportune for introducing this form of glassware in a number of other forms suitable for semi-indirect lighting, for which, with its beautiful pearly-white appearance, it is particularly suitable.

A new folder, artistically printed in colours, has just been issued by the Company, and contains illustrations and prices

FIG. 1.—VELURIA "URNOLITE."

FIG. 2.—VELURIA DISH.

of the various forms of Veluria glassware for semi-indirect lighting. Several patterns of semi-indirect bowls, in diameters ranging from 12 in. to 20 in., suitable for single Mazda lamps of from 40 to 400 watts, are included, in addition to Veluria spheres, "Urnolites," and the more familiar patterns of direct-lighting reflectors. The back cover contains illustrations and prices of a number of special fittings suitable to their glassware. Two examples are illustrated here, and we may mention that the prices at which they are listed are quite moderate.

**Guarantee of Goods Supplied.**—In the Shoreditch County Court last week the Splitdorf Electrical Co. (City Road, E.C.) sued Mr. F. W. Baker, of Stourbridge, for £3 owing on an account for a motor-car electric lighting outfit, which had been withheld owing to alleged faultiness of the battery forming part of the equipment. The defence contended that there was no guarantee of the battery, and that it had been treated improperly. After some argument the Judge found that the battery had been used properly, but had fallen to pieces, and that there was an implied warranty with its sale. Judgment with costs was given for defendants.

## SIEMEN'S CABLES AND JOINT BOXES

TWO very comprehensive new lists have been issued by the cable department of Siemens Bros. & Co., Ltd. (Woolwich), one dealing with paper-insulated cables and the

for wire-armoured cables. It will be seen that the sheathing wires are clamped to the box by means of a tinned brass plate, held in place by a heavy cast-iron clamp. When the cable is double wire-armoured, the wires of the inner sheathing are passed through the plate and flanged out against the box end. The outer sheathing wires are then flanged out, and clamped between the brass plate and the outer cast-iron clamp. The brass plates are connected by a copper bonding strap or strand, and a thoroughly good and efficient bond between the cables entering the box is thus formed which is not dependent in any way on the conductivity of the cast-iron box, as the galvanised iron wires make excellent contact on the sides of the brass plate. In order to

FIG. 1.—WALL TYPE TRANSFORMER BOX.

FIG. 3.—STRAIGHT-THROUGH JOINT BOX, SHOWING METHOD OF BONDING ARMOURING.

FIG. 2.—3,000-WATT TRIFURCATING BOX.

other with joint boxes. Paper-insulated cables are dealt with of every class up to 11,000 volts, and some very fine examples are illustrated. The interest is also added to by the views of the works and testing rooms. The cable joint-box list is one of the most comprehensive that we have seen, and includes full descriptive information on feeder pillars, disconnecting fuse and link boxes, sealing ends and end dividing boxes, straight joints, tee and service boxes, house service fuse boxes, crane connection boxes, mining gear, and general accessories.

Among the items to which attention may be drawn are the disconnecting fuse boxes with standard porcelain-handle fuses, and fittings effectively insulated by substantial porcelain insulators carried in a metal plate, and with their tops standing above the compound level. In Fig. 1 is shown a neat design of transformer wall box for circuits up to 2,200 volts. This is also made for D.P. fuses. A very complete series of end dividing boxes is included. One of these, a vertical 3,300-volt box, for mining cable, is illustrated in Fig. 2. It will be noticed that these boxes are designed to be used with bare copper connections, the deterioration of the india-rubber connections due to the presence of ozone being avoided. The end boxes are sufficiently complete to enable engineers to select standard articles to suit any relative position of cable trench and switchboard. An end dividing box, and inverted boxes for overhead lines, are also listed for pressures up to 20,000 volts. Other interesting items are the special crane boxes, which the firm has supplied for many years in large numbers for use at home and abroad on quays, docks, &c.

A separate section is devoted to mining accessories, while the Home Office Regulations for the use of electricity in mines is given *in extenso* in an appendix, which forms a very useful feature of this list. Fig. 3 illustrates a straight-through joint-box, and shows the standard bonding method adopted

ensure that the lead sheathing is also earthed, it is independently connected by a copper strip clamp at each end of the box.

## THE NIGHTINGALL ELECTRIC COOKER

AN interesting form of electric cooker provided with automatic means of heat regulation is described in a new leaflet issued by the General Electric Co. The Nightingall

FIG. 1.—NIGHTINGALL OVEN.

FIG. 2.—NIGHTINGALL STEAMER.

oven, which is shown open in Fig. 1, is of substantial construction, and is double-cased and lagged with a three-inch

thickness of heat-insulating material. The heating element, which is rated at 1,800 watts, is placed at the bottom. It is easily removable, and is protected by a wire frame. The most interesting part of the apparatus is the heat-regulating arrangement. A thermometer in a slot at the back of the cooker is fitted with five platinum contacts which represent the common terminal and steps of 200°, 300°, 400°, and 500° F. As the mercury rises in the thermometer, it brings into action a solenoid switch situated in the front of the cooker, and this switch cuts off current as soon as the heat of the oven has arrived at the predetermined temperature. A multiple-contact switch puts any one of these contacts into action, so that the oven can be kept at any one of the temperatures mentioned above at will.

The Nightingall steamer (Fig. 2) is constructed on similar lines to the oven, as far as the body is concerned, but is smaller. It is also automatically heat-controlled, but instead of four temperatures like the oven, it has only two—high, which equals a steam pressure of about 2 lb., and low, which is just about boiling point. The door is well lagged to prevent undue waste of steam. The current consumption is 800 watts only. In the bottom of the steamer is a well or water-containing space in which is placed an immersion heater, the connection to which is made in a joint at the back.

### A TALE OF TWO MOTORS

THAT the electric motor is of sturdy construction and capable of withstanding the most disadvantageous conditions is a claim that has been frequently made, and its validity is well borne out by the following example which has been sent us by the British Thomson-Houston Co., Ltd. (Rugby).

Two 10-h.p. squirrel-cage induction motors at the works

MOTORS IN WOODEN ROOF PRACTICALLY UNDAAGED BY FIRE.

of Samuel Wheeler & Sons, Ltd., Smethwick, were employed to drive a number of machine tools, and were mounted on beams in the wooden roof of the building. Just over a week ago a fire broke out, by which a large portion of the roof was destroyed. The two motors, although not actually in the fire, were so near as to be in danger of suffering serious damage from the intense heat, the roof truss on one side of them being totally destroyed, while that on the other side

was badly charred. A steady stream of water was therefore directed upon the motors by the fire brigade, and, as these were of the ordinary protected type, the windings received a severe drenching. Half-an-hour later, when the fire was finally subdued, it was found that, although the motors were thoroughly drenched and had been subjected for half-an-hour to the action of the smoke and steam emitted from the burning roof when the hose was played on it, they started up quite satisfactorily when the current was switched on. The two machines in question were manufactured and supplied by the B.T.H. Co. nearly two years ago, and, we are informed that they had given no trouble whatever until the outbreak of fire, and still continue to give every satisfaction.

### SPRAYERS FOR ENAMEL

WE have on more than one occasion referred to the economies which can be effected by the use of mechanical sprayers in distributing lacquers, paints, varnishes, &c., over large surfaces, and to the apparatus for this purpose supplied by the Fredk. Crane Chemical Co. (Armoury Close, Bordesley Green, Birmingham). The firm have now introduced a special sprayer for use with celluloid enamels, which gives a particularly fine even finish. Those interested are invited to apply for a copy of a descriptive booklet, or to attend demonstrations at the Company's central depôt, 22 Newhall Hill, Birmingham.

**Hotel Lighting.**—The Midland Adelphi Hotel at Liverpool is equipped with electric light fittings manufactured by the General Electric Co. (67 Queen Victoria Street, E.C.) in the following apartments. Main hall, entrance hall, French restaurant, dining-room, Sefton room, grill room, banqueting room, Masonic temple and annexe, lower lounge, smoking room, American bar, all bedrooms, toilets, and corridors, &c. The bedroom lighting is particularly worthy of notice on account of the restful effect produced. In addition to handsome bronze brackets over the beds, semi-indirect fittings are provided for the main illumination, consisting of Osram lamps in heavily moulded "Equiluxo" glass bowls suspended by silk cords.

**The Laboratory of the American National Electric Lamp Association.**—We are informed by Mr. E. P. Hyde, Director of the Physical Laboratory of the National Electric Lamp Association, will in future be known as the "Nela" Research Laboratory, national lamp works of the General Electric Co., Nela Park, Cleveland, Ohio, and its Abstract-Bulletin and other publications will appear under this name.

**"Mazda House News."**—The April issue of this popular little journal is now before us, and contains, among numerous illustrations, a number of examples of new methods of effecting indirect lighting by concealed reflectors, as well as other technical and humorous items. The possibilities of half-watt lamps for photographic work are dealt with, and details are given of the special Mazda focus lamp for optical and projection work.

**John E. Raworth,**  
Queen Anne's Chambers,  
30, Broadway, Westminster, London, S.W.  
Chartered Patent Agent

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Aylesbury.**—A Local Government Board inquiry was held last week concerning a loan of £21,323 for the Council's electric lighting undertaking.

**London: Hammersmith.**—The Electricity Department requires air-cooled static transformers and earthenware cable ducts. Borough Electrical Engineer. May 27th. (See advertisement on another page.)

**Hampstead.**—The following are the details of additional plant referred to in our last issue:—One 1,500-kw. mixed-pressure turbo-alternator, £4,700; cooling tower, tanks, and foundations, £1,800; condenser and pipework, £800; cables, switchgear, £300.

**Woolwich.**—The Local Government Board has sanctioned a loan of £18,000 for electrical extensions.

**Leeds.**—Water-tube boilers, mechanical stokers, economisers, induced-draught plant, &c. Manager, Electricity Department. June 10th. (See advertisement on another page.)

**Liverpool.**—Twelve months' supply of electrical fittings for the Liverpool overhead railway. General Manager, June 2nd.

**Manchester.**—Twelve months' supply of electrical stores, including dynamo brushes, lamps, cables, &c.

**Rangoon.**—The Rangoon Electric Tramway & Supply Co. is issuing new capital in order to lay down the necessary plant to meet increasing demands.

**Skelton and Brotton.**—The L.G.B. has sanctioned a loan of over £9,000 for the electric lighting scheme on condition that the Board of Trade give their consent to overhead wires.

**Stockport.**—Additional plant is to be installed at the power station.

**Sunderland.**—Increasing applications for electric power are coming in; one large power user has applied for an increased supply, and a fifteen years' agreement has been arranged, commencing with 425 kw., and for a maximum of 1,000 kw. An expenditure on low-tension distribution cable will shortly be made.—The Parks Committee has applied for a supply of current for additional illumination, and it is proposed to utilise from 800 to 1,000 lamps.

**Walsall.**—It is understood that the Electricity Committee will ask the Corporation to adopt the recommendation of Mr. E. M. Lacey, the Consulting Engineer, to erect a new power station at an estimated cost of £74,850.

### Wiring

**Edinburgh.**—Electric lighting of King's Park School. Architects, Crawford & Cumming, 41 George Street. May 18th.

**London: L.C.C.**—760 wiring points at Furzedown Training College, Tooting, S.W. (See an advertisement on another page.)

**St. Marylebone.**—The Guardians invite tenders for the electric lighting of the infirmary at Rackham Street, Ladbroke Grove. Clerk to Guardians, Northumberland Street, W. May 18th.

**Monmouth.**—Electric lighting of the Salisbury Club, Corporation Road.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Carlisle.**—New technical school. Town Clerk.

**Blackburn.**—Convalescent home (£3,000).

**Bournemouth.**—A £60,000 pavilion scheme has been inquired into by the Local Government Board.

**Croydon.**—Twelve houses, Raymead Avenue. C. Banks, 16 Oakfield Road.—Twenty-two houses, Enmore Avenue, J. B. Hemmings, Addiscombe.—Forty houses, Parkview Road, A. C. P. Duckit, 24 Sherwood Road.—Twenty-six houses, Galpin's Road, D. Weightman, 78 North End.

**Falkirk.**—Extensions to infirmary.

**Manchester.**—Headquarters for East Lancashire Territorial Association. Secretary, National Buildings, St. Mary's Parsonage.

**Newcastle-on-Tyne.**—New town hall.

**Nuneaton.**—Extensions to High School for Girls (£8,000).

**Sheffield.**—Cinematograph theatre. Architect, J. E. Whitehead, 38 Bank Street.

New school, Northfield Road. Secretary, Education Committee.

**Stretford.**—Erection of St. Peter's Church. Architects, Woodhouse & Howard, 86 Mosley Street, Manchester.

**York.**—Elementary school at Bilton. Architect, F. Raney, 24A Coney Street.

### Miscellaneous

**Ashton-under-Lyne.**—Two electric lifts for the workhouse hospital at a cost of £666.

**Australia.**—The Melbourne City Council requires 1,132,000 arc-lamp carbons. Specification at Messrs. McIlwraith, McEacharn & Co., Bilter Square Buildings, E.C.

**Dublin.**—A.C. prepayment meters. City Electrical Engineer. May 25th. (See advertisement on another page.)

**Morecambe.**—The electrification of the tramways is being considered.

## TENDERS RECEIVED AND ACCEPTED

**Belfast.**—Among the contracts for stores accepted for the coming year are the following:—Ediswan carbon lamps; G.E.C. metal-filament lamps and fuses; B.I. & Helsby Cables and A. Wiseman, overhead line materials; Callender's cables; W. H. Keys, bitumen; India-Rubber Co., tapes; Dussek Bitumen Co., joint-box compound; W. Lucy & Co., feeder pillars; Sloan Electrical Co., arc-lamp carbons; Doulton, troughing; Chamberlain & Hookham, meters; Venner, time switches; and Reason maximum demand indicators.

**Devonport.**—The tender of Messrs. James Howden & Co. has been accepted for a 1,250-kw. Howden-Siemens turbo-alternator, and that of Messrs. Bruce Peebles & Co. for motor-converters.

**London: G.P.O.**—An order has been placed with Siemens Bros. Dynamo Works for Wotan drawn-wire lamps up to and including 50 c.p.

**Torquay.**—The tender of Messrs. Babcock & Wilcox has been accepted for boiler plant at £3,352.

**Wallasey.**—The following tenders have been accepted:—Turbo-alternator, British Westinghouse Co.; boilers, Babcock & Wilcox; economiser, E. Green & Sons; E.H.T. cables, British Insulated & Helsby Cables; switchboard, Crompton & Co.; overhead crane, Carrick & Sons; rotary-converters, British Thomson-Houston Co.

## APPOINTMENTS AND PERSONAL NOTES

Dr. T. E. Stanton, Superintendent of the Engineering Department of the National Physical Laboratory, has been elected a Fellow of the Royal Society.

Mr. G. Nicolson (Chief Assistant Engineer, Weymouth) has been awarded the Dorset Field Club's "Cecil" silver medal and £5 for an essay on the production of electricity for domestic purposes.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £65 5s. to £65 15s. (Last week, £65 15s. to £66 5s.)

The Midland Electric Corporation (1900, Ltd.) is being wound up voluntarily.

A first and final dividend of 8s. 10d. in the pound is to be paid in the bankruptcy of C. Blake, trading as the Bilston Electric Co.

**New Branch Office.**—Fraser & Chalmers, Ltd. (3 London Wall Buildings, E.C.), have opened a branch office in Manchester, at 90 Deansgate.

**Change of Address.**—E. G. Appleby & Co. have removed to more extensive premises at 12 The Broadway, Westminster.

**Bankruptcies.**—Lord Templetown, who figured in the London Bankruptcy Court last week, started in 1904 as an electrical engineer in Craven Street, Strand, as Dorrington & Co. According to the statement made to the official receiver, very little business was done, and the Company then moved to 17 Victoria Street, S.W.

The bankruptcy of Mr. Harry Horne, which was inquired into at the London Bankruptcy Court last week, was attributed partly to the non-success of the Bryant Trading Syndicate, in connection with which a number of loans had been guaranteed by Mr. Horne.

## LOCAL NOTES

**Bristol: Dispute with Wiring Contractors.**—The Bristol Electrical Contractors' Association and the Corporation Electricity Department are in conflict as to the manner in which the present arrangement between the two parties is carried out. The contractors now work to a specification compiled by the Department, which, however, supplies the lamps, fittings, switches, &c., and takes the profit upon them as some recompense for having to maintain a showroom. The contractors complain that this method leaves very little profit, if any, to the contractors, who have to take all the responsibility for carrying out the work. Mr. H. Faraday Proctor, the City Electrical Engineer, has replied to the effect that the present arrangement has been forced upon the Council by the different methods carried out by various contractors, and that he is not at all sure he is justified in giving out to contract even so much of the work as is done at present. The matter has been before the Electricity Committee, which agrees with Mr. Faraday Proctor that no change should be made in the present arrangement.

**Burton-on-Trent: Assisted Wiring Scheme.**—In reporting a net profit of £3,055 for the past year's working on the electricity undertaking, the Borough Electrical Engineer says there is no doubt that with an assisted wiring system the sale of electricity for lighting would increase at a very rapid rate. There has been an increase of 62 per cent. in the sale of current for heating and cooking purposes for 1913-14, and it is noteworthy that, although the total output increased by approximately 400,000 units, the actual working expenses decreased by £97.

**Edinburgh: Expenditure on New Power Station.**—The Electric Lighting Committee proposes to spend an additional £59,250 on capital account during the coming financial year, of which £30,000 will be the first instalment of the cost of the new generating station at Portobello.

**Kingstown: Gas Co.'s Defeat.**—We reported in our last issue the defeat of the Dublin & Alliance Gas Consumers' Co. in its application for electricity powers in Kingstown, Dalkey, and Blackrock. Since then the Gas Co. has suffered another defeat. The Dublin Southern District Electric Supply Co. has now been granted an order for Kingstown, with an option to the U.D.C. to take over the powers within six months. At the close of the proceedings on this order, and in consequence of the option given to the Council to purchase the Gas Co.'s order, an application was made for the insertion of the "Northumberland" clause in the event of the Council taking over the powers. Here, again, the Gas Co. was unsuccessful. The fight between the Gas Co. and the Dublin Southern District Electric Supply Co., with which Mr. W. M. Murphy is connected, has been a very long and costly one, and has been mainly due to the endeavour of the Gas Co. to prevent competition from electricity supply by another company than itself.

**Leeds: Charging for Electric Vehicles.**—At the last meeting of the Corporation, Mr. R. Armitage, M.P., moved to refer back a recommendation that current for charging electric vehicles should be charged at 1d. per unit. He contended that this is not a rate which will encourage the use of electric battery vehicles in Leeds, and urged the adoption of a lower one. The Chairman of the Committee, however, pointed out that 1d. per unit was not intended to be a definite rate for the purpose. It related in this case merely to the charging of one vehicle, and if other people came along the Council could be assured that the Committee would take a business-like view of the matter.

**London: Hammersmith: Thames Circulating Water.**—Owing to some cleaning operations up the river, the strainers for the river circulating water at the electricity works have had to be

cleaned several times a day. At low tide this is done by men wearing waders, but at other times by the use of a boat, which is expensive and unsatisfactory. When the condensing plant was put down originally it was suggested that the pipes should be arranged so that either pipe could be temporarily used as a discharge pipe. This was not considered necessary at the time, but it is now to be done.

**I.M.E.A. Meeting.**—The Chairman and Vice-Chairman have been chosen as delegates, and their convention fees will, as hitherto, be paid out of the funds of the undertaking.

**St. Pancras: M.E.A. Delegates.**—Alderman G. Hickling and Councillor W. C. Wood have been appointed delegates to the I.M.E.A. meeting next month, and they have undertaken to pay their own expenses.

**Loughborough: Meeting Gas Competition.**—The Chairman of the Gas Committee has been making comments upon a proposal by the Electrical Engineer, which will have the effect of strengthening the competition with gas. The proposal of the Electricity Committee is to lay mains in a certain new street, and to supply villas and cottages there with lighting current at a fixed charge per week. The Chairman of the Gas Committee frankly states that this will affect the Gas Department, and the whole theme of his remarks was that any serious efforts made to develop the electrical undertaking would make the gas undertaking a non-paying concern. The comments in question do not appear to have met with a great deal of sympathy in the Council.

**Manchester: Purchase of Trafford Power Co. Refused.**—The bill of the Corporation, to which reference was made last week, has now been finally dealt with by a House of Lords Committee, presided over by Lord Barnard. The Committee refused to allow the Corporation to purchase the undertaking of the Trafford Power & Light Supply Co., and also struck out of the bill clauses extending the Corporation's area of supply into Stretford, Trafford Park, and Davyhulme. The proposal to erect a new power station at Davyhulme, however, is unopposed, and remains in the bill.

**Scarborough: Purchase of Supply Co. Abandoned.**—As we have previously announced, the Corporation has been inquiring of the Scarborough Electric Supply Co. as to a possible purchase of the Company's undertaking. As the result, however, of a communication just received from the Company, the Property Committee, which has had the matter in hand, recommends that no further steps be taken.

**Tunbridge Wells: Supply outside Area.**—The Council has received sanction under the Electric Lighting Act of 1909 to supply certain premises outside its area. Following its usual practice, the Board of Trade has informed the Council that if it becomes necessary to supply other premises in the same district, it would be better for the Council to promote an electric lighting order for a general supply in this district.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Electric Construction Co.**—A 6 per cent. dividend is recommended on the ordinary shares for the ten months to March 31st.

**Craigpark Electric Co.**—A 6 per cent. dividend is recommended on the ordinary shares for the year to March 31st, carrying forward £1,941.

**Kent Electric Power Co.**—There was a net profit of £4,539 for 1913, and the directors propose to pay all arrears of dividend on the 6 per cent. cumulative priority shares to December, 1912, and also the same dividend for 1913, leaving a balance of £155 to be carried forward.

**British Thomson-Houston Co.**—There was a net profit of £77,044 for 1913, and of this the sum of £64,100 has been appropriated to depreciation and reserve. The balance of £12,944 is carried forward. The Company's works at Rugby, Coventry, and Willesden are reported to be in good condition, and the manufacture of switchboards and appliances has now been completely concentrated at Willesden. The financial result is a marked improvement over previous years.

**Obituary.**—The death occurred at Antibes, on Saturday, of M. Paul Héroult, the French electro-metallurgist. His name is well-known from the Héroult furnace, used to a considerable extent for electro-metallurgical work. He patented a method of manufacturing aluminium in the electric furnace in 1887, which was first tried on a commercial scale in Switzerland in the following year. His electric steel furnaces are in use in America, as well as Great Britain.

## SUMMARY

THE Electrical Trades Union are insisting on extravagant demands with regard to wiremen's wages, etc., in Liverpool, and the newly-formed Liverpool and District Electrical Masters' Association definitely refuse to concede them. (Page 278.)

THE L.C.C. has voted a further £3,500 for its investigation with regard to the London Electric Supply Scheme. A motion that the Committee should report definitely early in July was defeated at the meeting of the Council on Tuesday. (Page 278.)

REDUCTION gearing is coming into use for driving slow-speed continuous-current generators by high-speed turbines. A set in which this is done at the Horseferry Road Station of the Westminster Electricity Supply Corporation is described in an illustrated article. (Page 279.)

AMONG the Papers before the Iron and Steel Institute at the meeting this month, one, by Sir R. Hadfield and Prof. B. Hopkinson, dealt with the magnetic properties of manganese steel; and another, by Prof. Benedicks, gave results of some experiments on ferro-magnetic mixtures. (Page 280.)

WE give the result of the ballot for the new Council of the Institution of Electrical Engineers, and explain the circumstances which have led to the dissolution of the Industrial Committee. The membership of the Institution has decreased slightly since last year. A list of the premiums awarded is given, and other information from the Annual Report of the Council, which will be considered at the Annual General Meeting to-day. (Page 281.)

THE final programme of the Birmingham convention of the Incorporated Municipal Electrical Association has now been issued. (Page 281.)

THE Oxford City Council has decided to agree with the National Electric Construction Co. for the institution of a service of motor omnibuses instead of reconstructing the horse tramways for electric traction.—The Leeds Corporation's proposal to run a trolley omnibus line to Wharfedale has been passed by Parliament.—Extensions are being made to the Ramsbottom trolley-omnibus scheme, and experiments are being made with this form of electric traction by the Shanghai Electric Construction Co. (Page 282.)

WIRELESS telephony has been accomplished between Nauau and Pola. The Cefndu transatlantic wireless station, near Carnarvon, is approaching completion. (Page 282.)

THE heating of transformers and the meaning of the term heating time-constant is discussed in our Questions and Answers columns. (Page 283.)

AMONGST the specifications published last week were some relating to automatic telephony, manufacture of tungsten, and the ventilation of A.-C. motors. Three lapsed patents have been restored. A patent for electrolytic bleaching expires this week after a life of fourteen years. (Page 284.)

SEVERAL new installation accessories are described in our Trade Section, which also contains articles on church lighting, telephone apparatus, arc lamp lowering gear, a new thermopile and a fire extinguisher. (Pages 285 to 287.)

LARGE schemes of electrical extensions are to be carried out at Walsall, Watford, Leigh (Lancs.), Bury, and Stockport; cable is required at Cleckheaton; water-tube boiler and cooling tower at Darlington; motor-driven induced draught plant at Leeds; two 2,000 kw. steam turbines at Oldham; switchgear at Shanghai; and oil-break switches in Wellington (N.Z.). (Page 288.)

A GENERAL improvement in trade conditions was reported at the annual meeting of Callender's Cable & Construction Co. last week. (Page 288.)

THE Hove Corporation has been advised to retain the late Company's undertaking in its own hands, but two recent offers to lease it are being considered.—It has been decided to retain the separate control of the Glasgow tramways and electrical undertakings.—The Carlisle Corporation has decided to enforce a minimum of 30s. per annum upon its electric lighting consumers.—An investigation is to be carried out as to street lighting generally in Edinburgh.—The power load at Rotherham has been doubled during the past year.—Mr. Duncan Watson has presented the Marylebone Electricity Supply Department with an electric vehicle chassis. (Page 289.)

## ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MAY 21st.

*Institution of Electrical Engineers.*

5 p.m. Annual General Meeting.

*Illuminating Engineering Society.*

7.30 p.m. Annual General Meeting. "The Nomenclature and Definitions of Photometric Quantities," by A. P. Trotter.

FRIDAY, MAY 22ND.

*Physical Society.*

5 p.m. At Imperial College of Science. The Agenda includes "Experiments with an Incandescent Lamp," by C. W. S. Crawley and S. W. J. Smith.

SATURDAY, MAY 23RD.

*Association of Mining Electrical Engineers.*

2 p.m. Notts and Derbyshire Branch. Visit to Grassmoor Collieries.

MONDAY, MAY 25TH.

*Association of Consulting Engineers.*

4.30 p.m. Annual meeting at Caxton Hall, Westminster, S.W.

THURSDAY, MAY 28TH.

*Institution of Railway Signal Engineers.*

2.30 p.m. At Institution of Electrical Engineers. "American Signal Practice as Compared with British Practice," by A. H. Rudd.

### The London Electrical Engineers.

Headquarters (46 Regency Street, S.W.) open Sats. till noon.  
Rating Exam. for all Cos. from 7 to 10 p.m. every Wednesday.  
Annual course of musketry at Purfleet for all Companies, Wednesday, May 27th.

(TO-DAY) THURSDAY, MAY 21ST, C. Co. FRIDAY, MAY 22ND, D. Co.  
MONDAY, MAY 25TH, A. Co. TUESDAY, MAY 26TH, B. Co.  
THURSDAY, MAY 28TH, C. Co. FRIDAY, MAY 29TH, D. Co.

### WIREMEN'S WAGES IN LIVERPOOL

AS stated in our issue of March 26th (p. 174), the Liverpool wiremen are demanding an increase in their wages from 9½d. to 1s. an hour, and other concessions. We also announced in the same issue that an association of masters was being formed to deal with the situation. This will be a permanent body—the "Liverpool and District Masters' Association," and over seventy firms have joined it. The

Chairman is Mr. A. E. Gregson (Northern Electrical Ventilating Co.), the Vice-Chairman, Mr. H. T. Boothroyd, the Hon. Sec., Mr. F. G. Pulford (108 and 110 Whitechapel, Liverpool), and the Hon. Treasurer, Mr. S. McLeigh (John Hunter & Co.). The other members of the Committee are:—

Mr. F. W. Smith (Herd & Smith), T. W. Robson (T. W. Robson & Sons), A. E. Chesters, J. O. Rhodes (Electric Light & Engineering Co.), J. Scott (J. Scott, Ltd.), J. Boulton (John Boulton & Co.), H. L. Downes (Downes & Davies), F. B. Hellon (Hellon & Co.). An entertainment committee has also been elected to look after the interests of the members on the social side, and the first smoking concert will be held on Friday, May 29th, at 7.45 p.m., at St. George's Restaurant; all intending members are cordially invited.

The Hon. Sec. points out that the Electrical Trades Union, which is organising the disturbance, has had to be content with far lower wages for its members in London and Manchester than those demanded in Liverpool. In London the men on strike are only asking for 10½d. an hour, and in Manchester a settlement has been arrived at for two years for 9½d. an hour.

The members of the Masters' Association are unanimous in their resolve not to grant these demands, and at a conference with the delegates of the E.T.U., held last week, the Union officials were informed that none of their demands could be considered. The masters state that, in the event of a strike, they are fully organised to carry out the most urgent work on hand with non-Union labour.

**The London Electricity Supply Scheme.**—At the meeting of the L.C.C. on Tuesday, a resolution was moved instructing the Special Committee on London Electricity Supply to lay a report before the Council not later than the second Tuesday in July. The main reason put forward in favour of the resolution was that there has been too much delay in regard to this important matter, and that some definite scheme should now be placed before the Council following on the report by Messrs. Merz & McLellan. Eventually the resolution was defeated, it being stated that the needs of the Council will be met if a scheme is prepared in time for the next Parliamentary session. The discussion arose in connection with a vote of £3,500 for further investigation. It was mentioned that the Special Committee has been taking expert evidence for twenty-eight months.

The Industrial Committee of the Institution of Electrical Engineers is unable to make progress.

## A GEARED TURBO-GENERATOR

**T**HE use of gearing in conjunction with steam turbines has been adopted to a considerable extent for both land and marine purposes. In the latter case its function is to permit of the turbines and propellers both running at speeds conducive to their highest possible efficiency—speeds which are high in the case of the turbine and low in the case of the propeller. The application of the geared turbine to the drive of elec-

also connected in series to reduce the voltage on each commutator. With the general increase in the size of generating units, however, there is a growing need for some other solution to the problem, and practically speaking the choice may be said to rest between using a turbo-alternator in conjunction with a rotary converter or providing a speed reduction gear between the turbine and the dynamo; for there is no electrical difficulty

FIG. 1.—GENERAL VIEW OF 1,500 kW. GEARED TURBO-GENERATOR.

trical generating plant was also developed simultaneously. In the case of alternating-current plant, the speed conditions which suit the turbine can generally be met satisfactorily by the generator, and turbo-alternators of large size running at 3,000 r.p.m. are in use with successful results. The problem with continuous-current plant is different, however. Large high-speed continuous-current generators present difficulties in design from both mechanical and commuta-

in constructing large continuous-current units of high efficiency running at moderate speeds. The former alternative was considered desirable for special reasons in the case of two new sets recently ordered for the MacDonald Road Station, Edinburgh, but for the set we are about to describe at the Horseferry Road Station of the Westminster Electric Supply Corporation, considerations of capital cost in conjunction with the capitalised value of the saving in steam consumption

FIG. 2.—PLAN SHOWING RELATIVE SIZES AND POSITIONS OF TURBINE, GEAR CASE, AND GENERATOR.

tion points of view, and as high an efficiency cannot be reached with them as can be with machines running at lower speeds, consequently a sort of compromise has hitherto been arrived at. Turbines running at rather lower speeds than are required to give the highest steam efficiency have been employed, and the electrical portion of the set has often been divided into two separate machines coupled in tandem and sometimes

possibly led to the decision of Messrs. Kennedy & Donkin, the consulting engineers, to adopt a geared turbine.

Quite a number of geared turbines have been supplied by the Parsons Co. for land purposes, the first example being a turbine geared to a rolling mill in Scotland, which has been in continuous successful operation for three years. There are also three Indian jute

mills driven by a combination of gearing and ropes. A 4,000 kw. continuous-current set has also been running at the Bankside Power Station of the City of London Electric Lighting Co., the turbine running at 2,400 revs. and the tandem dynamos at 370 r.p.m. The plant at Horseferry Road is of 1,500 kw. capacity, and has been running regularly since March 31st.

A general view of the set is seen in Fig. 1, and a plan showing its general arrangement is given in Fig. 2. The difference in its appearance from the more familiar style of generating set is very striking, continuing as it does the general tendency of the steam end of the set to get smaller and smaller in proportion to the electrical end. The turbine, which together with the gearing was made by C. A. Parsons & Co., Ltd., is of the impulse-reaction type, with a single initial impulse stage and the usual many rings of reaction blading in one cylinder. It is supplied with steam at 200 lb. per square inch with 150° F. superheat, and runs at 300 r.p.m. The general construction and governing arrangements are in accordance with Messrs. Parsons' standard practice.

As the dynamo runs at 300 r.p.m., the gearing is of ten to one ratio. It is on the same general lines as the Parsons' marine gearing, consisting of two wide helical gear rings with the slope in opposite directions to balance the end thrust. The pinion is solid steel, and the gear-wheel consists of a cast-iron drum, over which are shrunk and keyed the two mild steel rings, each 15 in. wide and about 6 ft. in diameter, in which the teeth are cut. These gears are cut by Sir C. A. Parsons' "creeping-table" method, which he has fully described in Papers read before the Institution of Naval Architects. The gear is lubricated by oil squirted continuously at the line of contact of the teeth. This oil comes from the same pressure system that supplies the bearings. A flexible coupling is provided between the turbine and the pinion shaft, but the armature of the generator is coupled rigidly to the gear wheel shaft. In some other makes of turbine gearing floating bearings are used for the pinion shaft, enabling it to take up its own position, but Messrs. Parsons do not find this necessary, and, in accordance with their usual practice, have fitted solid bearings. The gearing runs wonderfully quietly considering its remarkably high tooth speed, and indeed the whole set is perceptibly quieter on full load than the older ungeared sets in the station.

The generator was manufactured by Siemens Brothers Dynamo Works, Ltd., has a rated output of 1,500 kw. at 400 to 460 volts at 300 r.p.m. It is a very imposing looking machine, with eighteen main poles and an armature about 8 ft. in diameter. It is fitted with commutating poles, and the main poles are laminated. The commutator, which is 4 ft. in diameter, is made in two sections to avoid excessive length of the segments.

The generator is designed on liberal lines as regards solidity and efficiency, and the rated output is such that the temperature rise is well within that guaranteed, and the machine will stand an overload of 25 per cent. for half-an-hour and of 40 per cent. for three minutes without injury or undue heating.

The set stands over its condensing plant in the usual way. A surface condenser, supplied by Willans & Robinson (Rugby), and fitted with the Parsons vacuum augmentor, is employed, and a 28½-in. vacuum can be maintained. A steam-driven air pump is used, supplied by W. H. Allen, Son & Co. (Bedford). The set necessitated extension in boiler plant, which took the form of one Babcock & Wilcox water-tube boiler of 20,000 lb. per hour evaporative capacity, with chain-grate stokers.

With regard to the steam consumption of the set we may say that the guaranteed consumption was satisfactorily realised on test, and a very good result was attained, showing an all-round economy, over a one week run, of about 20 per cent. on the 1,000-kw. direct-driven turbo-sets forming the original equipment of the station.

In conclusion, we wish to offer our thanks to Messrs. Kennedy & Donkin, consulting engineers, to whose specifications the work was carried out, and to Messrs. C. A. Parsons & Co., Ltd., and Siemens' Brothers Dynamo Works, Ltd., manufacturers of the plant, for kindly supplying us with particulars, and to Mr. G. Horley, resident engineer to the Westminster Electric Supply Corporation at Horseferry Road, for permission to inspect and photograph the set.

**Prosecution by London Firm.**—Three employees of Messrs. Duncan, Watson & Co., were charged with stealing, between February 1st and May 12th, from 31 Great Titchfield Street, W., a quantity of wire and fittings valued at £22. A cycle repairer of Berwick Street, Soho, was charged with receiving some of the stolen property, knowing it to have been unlawfully obtained. Mr. Freke Palmer prosecuted, Mr. Barrington Matthews defended. The manager of the prosecuting firm stated that on missing the articles from stock, he spoke to one of the accused, who then made a statement incriminating himself and two other employees. Some of the missing articles were found in the Berwick Street shop of the other accused. The prisoners were remanded, bail being allowed for the last mentioned, in the sum of £100.

## MAGNETIC PROPERTIES OF ALLOYS AND MIXTURES

ONE of the Papers read at the meeting of the Iron and Steel Institute recently described researches into the magnetic properties of manganese steel by Sir Robert Hadfield and Prof. B. Hopkinson. It is now well known that manganese steel containing about 12 per cent. of manganese and 1½ per cent. of carbon, when prepared in the ordinary way, is practically non-magnetic, but that if heated to a high temperature and slowly cooled, can be rendered magnetic. The influence of slow heat treatment is further studied in the present Paper. Samples heated for long periods at temperatures in the neighbourhood of 500° C. were tested magnetically (by a differential method, which compared their permeability with that of a standard piece of nearly pure iron) at intervals, and were found to exhibit a gradual rise in permeability, according to a curve asymptotic to a constant value varying with the temperature. Quenching the specimen did not destroy the magnetic quality thus created, but further heating at temperatures exceeding 640° resulted in a diminution of the magnetic quality at a rate more rapid the higher the temperature, until, at 750° C., the magnetic properties were practically removed in a few minutes. At intermediate temperatures the magnetic quality does not entirely disappear, but ultimately settle down to constant reduced value. The material in the ordinary non-magnetic condition, or in the magnetic condition induced by prolonged heating at 520° C., is unchanged by immersion in liquid air, but in an intermediate condition, after short heating at 500° C., it is rendered more magnetic by immersion in liquid air. It was also noticed that cold working makes the water-toughened material slightly magnetic. Heating and cooling curves showed a change point at about 650° C. The explanation of these effects appears to be that the stable form of the alloy at temperatures below about 750° C. is more or less magnetic, the proportion of magnetic substance present in the equilibrium state diminishing rapidly when the temperature approaches that figure. Above 750° C. the magnetism is all gone. From about 650° C. to 750° C. there is a critical range similar to that corresponding to the loss of magnetism in ordinary carbon steel. If the alloy be cooled from above this critical range, the tendency, as it passes through any lower temperature, is towards the attainment of the amount of magnetism proper to that temperature. But the rate of approach to equilibrium is so slow that even when the cooling takes several minutes, but very little of the magnetism is restored, and the effect produced is similar in kind to that produced by quenching a carbon steel. The important effect of the manganese is, apparently, this retardation of the attainment of equilibrium, rather than any very marked shift of the position of the critical range. The Paper also discusses the mechanical properties and micrographic structure of the material.

The magnetic properties of certain ferro-magnetic mixtures were investigated in another Paper by Prof. C. Benedicks (Stockholm), presented during the meeting. Magnetic measurements were carried out on ferro-magnetic, mechanical mixtures of magnetite (with quartz), iron (with copper), and nickel (with copper), the latter pressed together into solid bars. They proved, in agreement with older measurements, that the magnetic intensity shows a very distinct deviation from a rectilinear depending on the concentration. This is an experimental verification of a previous theoretical curve of the author's, which serves, at least on broad lines, to explain how the assumption of one gradually occurring molecular change (the increased presence of  $\gamma$ -iron with rising temperature in the  $\alpha$ -iron) can agree with the rapid falling of the magnetism within a certain interval.

**Celluloid.**—Further regulations regarding the premises where celluloid is made, worked, or stored have been issued in draft by the Home Office. According to these regulations, amounts of celluloid over 1 cwt. may only be stored in special fireproof chambers. The amount of celluloid in workrooms is to be kept as small as possible, and waste is not to be allowed to accumulate. Open lights and fires are not allowed in cinematograph film rooms, and smoking and the introduction of matches are forbidden in all cases where celluloid is present. Saws for cutting celluloid are to be kept constantly wet, and sealing-wax is not to be used for parcels containing celluloid. Various precautions regarding escape in case of fire are required.

**The "Point Fives."**—It is requested that all those attending the I.M.E.A. Convention who wish to come to the meeting of the "Point Fives" on June 18th, at the Grand Hotel, Birmingham, will send in their names to the Hon. Secretary, Mr. A. H. Seabrook (19 and 20 York Place, Baker Street, W.), as early as possible.

## INSTITUTION OF ELECTRICAL ENGINEERS

### The New Council.

The following is the result of the ballot for the six vacancies on the Council:—

**COUNCIL'S NOMINATIONS:**—*Elected:* Prof. B. Hopkinson, F.R.S., G. W. Partridge, W. H. Patchell, and W. B. Woodhouse. *Not Elected:* W. L. Preece, G. S. Ram, W. Slingo, and A. A. C. Swinton.

**OTHER NOMINATIONS:**—*Elected:* J. Christie and R. J. Wallis-Jones. *Not Elected:* F. Ayton and Haydn T. Harrison.

The other Members of Council are:—

J. F. C. Snell (*President*); W. Judd, C. H. Merz, J. S. Highfield, and C. H. Wordingham (*Vice-Presidents*); R. A. Chattock, F. Gill, W. Rutherford, A. H. Seabrook, Roger T. Smith, and Dr. A. Russell (*Members*); F. E. Berry, A. W. Martin, and Capt. E. O. Henrici (*Associate Members*); A. B. Anderson, E. Russell Clarke, and A. M. J. Ogilvie, C.B. (*Associates*); Robert Hammond (*Honorary Treasurer*).

In addition, the Chairman and a Past-Chairman of each Local Section are *ex officio* members of Council.

### The Industrial Committee.

In the Council's Report for the year, which will be presented at the Annual General Meeting to-day, it is stated that the Industrial Committee has been dissolved. The official explanation of this is that the Committee asked for changes in its constitution and enlargement of its powers to enable it to perform useful work, neither of which requests the Council felt itself to be in a position to grant, and they therefore dissolved the Committee. The facts of the matter are that the Committee found a decided want of sympathy with them on the part of the Council. Various recommendations, we believe, were put forward by the Committee and its members, only to be set aside either by the Council or to be withdrawn on the assurance of the Council's representatives on the Committee that they could not be passed for the reason that the recommendations were of a political or semi-political character, or that they dealt with matters in regard to which the various sections of the membership of the Institution might be in conflict. It is just this latter class of questions with which the Institution should be in the best position to deal, and it is to be regretted that the value of the Institution to the electrical industry should be limited by this statement of policy and by this unnecessarily broad conception of what are "political" issues. We can take two cases as examples. The dispute between the Electrical Contractors' Association and the Municipalities on the wiring question was brought before the Industrial Committee, and a compromise was arrived at which, we understand, only needed the official endorsement of the Institution to make it acceptable to both parties. Although the Committee had thoroughly gone into the matter and recommended the terms arrived at as fair to both sides, the Council refused to confirm the Committee's action. Another case, we have reason to believe, was an endeavour to take action with regard to flotations in the City of schemes for which foreign instead of British plant was to be employed. To take any effective steps in the matter it would have been necessary to invoke the aid of the Press for the purpose of propaganda, but sanction to this was also refused by the Council. Men who have to make a sacrifice to find time to give to Committee work are not likely to continue if they find that their work is constantly ineffective, and it is hardly to be wondered at that something in the nature of an ultimatum was presented, with the result that the Committee was dissolved.

### Decrease in Membership.

The membership of the Institution has decreased from 7,084 on May 1st, 1913, to 7,045 on May 1st, 1914.

### Premiums, Prizes, and Scholarships.

The following awards have been made:—

The Institution Premium, value £25, to Mr. S. Evershed, for his Paper, "The Characteristics of Insulation Resistance."

The Ayrton Premium, value £10, to Mr. F. Lydall, for his Paper, "Electric Locomotives."

The Fahie Premium, value £10, to Commandant G. A. Ferrié, for his Paper, "Application of Wireless Telegraphy to Time Signals."

The John Hopkinson Premium, value £10, to Mr. L. J. Hunt, for his paper, "The Cascade Induction Motor."

The Paris Premium, value £10, to Mr. B. Welbourn, for his Paper, "British Practice in the Construction of High-Tension Overhead Transmission Lines."

An Extra Premium, value £10, to Messrs. K. M. Faye-Hansen and J. S. Peck, for their Paper, "Current-Limiting Reactances on Large Power Systems."

An Extra Premium, value £5, to Mr. S. H. Holden, for his Paper, "The British Standard Specification for Consumers' Electric Supply Meters."

An Extra Premium, value £5, to Mr. F. J. Teago, for his Paper, "Experiments on Air-Blast Cooling of Transformers."

Students' Premiums have been awarded for the following Papers:—"Comparative Tests on Single-Phase A.C. Commutator Motors," by E. A. Richards and D. Dunham. "The Electrical Equipment of Collieries," by H. S. Ripley. "Diseases and Troubles experienced with Transformers," by J. Lindley Thompson. "The Possibilities of Electric Traction on Railways," by J. L. Moffet. "The Laws of Dielectrics," by W. S. Flight. "The Automatic Control of Electrical Generators by means of Automatic Pressure Regulators," by A. Arnold and E. L. M. Emtage.

The Council have awarded a Salomons Scholarship of the value of £50 to C. H. Stubbings, of King's College; and two David Hughes Scholarships of the value of £50 each to John G. Wellings, of the Finsbury Technical College, and to James Mould, of University College, London, respectively.

### Miscellaneous.

Among other matters dealt with in the Council report are the following:—

**Meetings for Specialised Papers.**—The Council have had under consideration the question of some reorganisation of the meetings in order to stimulate interest in the various branches, and to encourage members to take a more active part in discussions on subjects which are of special interest to them. They have therefore appointed a number of Sectional Committees to advise the Council as to the selection of Papers and promotion of discussions of a specialised nature. These will take the place of the Informal Meetings, which were introduced two sessions ago without much success.

**Local Centres Abroad.**—The report states that local centres already exist in Calcutta and Cape Town, and the Council have recently sanctioned the formation of one at Hong Kong.

**Kelvin Memorial.**—The surplus from the fund collected for the Memorial Window to Lord Kelvin is to be devoted to the establishment of a Kelvin Gold Medal to be awarded every three years as a mark of distinction achieved in engineering work of the kinds with which Lord Kelvin was especially identified.

**International Illumination Commission.**—The Council have appointed Messrs. W. Duddell, F.R.S., F. Bailey, K. Edgcombe, Haydn T. Harrison, and Professor J. T. Morris as delegates to the British National Committee, and are contributing equally with the Institution of Gas Engineers towards the expenses of the Committee.

**International Scientific Radio-telegraphic Commission.**—Particulars of the formation of this Commission were given in our issue of October 30th, 1913, page 607. The Institution has formed the National Committee for the United Kingdom of the following members:—Mr. W. Duddell, F.R.S., Dr. W. H. Eccles, Professor G. W. O. Howe, Sir Oliver Lodge, F.R.S., Dr. E. W. Marchant, Sir Henry Norman, M.P., Dr. S. P. Thompson, F.R.S. The first meeting of the Commission was held in Brussels on April 26th, and the delegates were Mr. W. Duddell, Dr. W. H. Eccles, and Dr. E. W. Marchant.

**Engineering Standards Committee.**—The number of representatives of the Institution on this Committee is to be increased to three, viz., Colonel R. E. Crompton, C.B., Messrs. J. F. C. Snell, and C. P. Sparks. In place of the existing Electrical Plant Committee an Electrical Sectional Committee is to be formed, representative of every electrical interest, and containing a predominating representation of the Institution.

**Scottish Local Section of the I.E.E.**—The annual report records eight meetings with an average attendance of 49. The membership of the section is 391, including 43 students. The following is the committee for next session:—*Chairman*, Mr. J. Lowson; *Vice-Chairman*, Mr. D. A. Starr; *Past-Chairmen*, Messrs. F. A. Newington, W. M'Whirter, and J. A. Robertson; *Chairman of Students' Section*, Mr. A. Page; *Ordinary Members of Committee*, Messrs. M. B. Field, J. H. Bunting, J. S. Nicholson, J. K. Stothert, J. F. Nielson, E. T. Goslin, G. Stevenson, W. L. Spence, J. E. Sayers, A. S. Hampton, and Prof. J. D. Cormack. *Hon. Secretary and Treasurer*, Mr. J. Taylor. *Assistant Honorary Secretary*, Mr. W. F. Mitchell. The annual summer outing this year will take the form of a steamer excursion to Arran on June 9th.

## THE BIRMINGHAM CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

THE full programme of the forthcoming I.M.E.A. Convention at Birmingham on June 15th to 25th, under the Presidency of Mr. R. A. Chattock (City Electrical Engineer), has now been issued. The principal arrangements are as follows:—

**Monday, June 15th.**—The Convention Bureau will open at the Grand Hotel, and in the evening an informal reception and smoking concert will be given by the Birmingham Entertainments Committee.

**Tuesday, June 16th.**—Meeting at Midland Institute to hear Mr. Chattock's Presidential Address and a Paper by Mr. W. A. Vignoles (Grimsby) on Commercial Development of Electric Supply to Towns of Moderate Size. After a lunch provided by the Birmingham Entertainments Committee, visits will be paid to the Witton works of the General Electric Co., and the works of Belliss & Morcom. The Summer Lane electricity works of the Corporation will also be open to inspection. In the evening the annual dinner will be held at the Grand Hotel. Visits will be arranged for ladies to Elkington's show-rooms and works and the Birmingham Art Gallery.

**Wednesday, June 17th.**—Meeting at Coventry, at which Mr. S. E. Fedden (Sheffield) will read a Paper on boiler-house plant. Visits will be paid in the afternoon to the Daimler Co.'s works, and to the Coventry Corporation electricity works. The following works will also be open to inspection: Coventry Ordnance; Triumph Motor Cycle; Coventry Chain Co., and B.T.-H. Co.'s meter works. The B.T.-H. Co. and Willans & Robinson will also convey members who desire to see their works at Rugby and back to Coventry during the afternoon. A visit will be paid by the ladies to Combe Abbey in the morning, and to places of interest in Coventry in the afternoon. A reception and dance will be held by the Lord Mayor of Birmingham in the evening.

**Thursday, June 18th.**—Meeting at Stratford-on-Avon. Mr. J. H. Bowden (Poplar) will read a Paper on Standardisation of Tariffs. An excursion to Warwick will be made in the afternoon. An open air fête will be held at the Botanical Gardens, Edgbaston, in the evening, followed by a "Point Fives" meeting at 10.30 at the Grand Hotel.

**Friday, June 19th.**—Annual General Meeting in the morning. Visit to the Summer Lane Station in the afternoon.

**Saturday, June 20th.**—Visit to Worcester.

## ELECTRIC TRACTION NOTES

By twenty-five votes to twelve the Oxford City Council, at a special meeting last week, decided to agree with the National Electric Construction Co. for the latter to provide a service of motor-omnibuses instead of reconstructing the existing horse tramways for electric traction. The Company has a Bill in Parliament this session with this object in view, and the agreement with the Corporation provides that the latter shall forego the liquidated damages to which it is entitled by reason of the Company not having carried out the terms of previous Acts of Parliament. The existing horse-tramway track is to be handed over to the Corporation for the purpose of renewal. If, in the future, the Corporation requires a service of electric tramways, the Company is to promote the necessary Bill upon terms to be agreed, or failing agreement, to be settled by arbitration.

The Shanghai Electric Construction Co. is experimenting with two trolley-omnibuses with a view to possible extensions should this system of traction prove satisfactory.

The Ramsbottom U.D.C. has ordered two additional trolley-omnibuses, owing to the amount of traffic which the existing routes have attracted.

The Leeds Corporation Bill has been considered by a House of Lords Committee during the week. Among the objects is one to construct a trolley-omnibus system to Wharfedale, and it is in respect of this that the Yorkshire Electric Power Co. is opposing on the question of power. The argument is that, as these lines will be outside the Leeds Corporation area, the Corporation should not be allowed to supply, in view of the fact that they are in the area of the Yorkshire Electric Power Co. The Committee has passed the scheme on the understanding that so far as the trolley-

omnibus portion of it is concerned, a contribution of 0.375d. per car mile is to be paid by the Corporation towards the capital expenditure in widening or reconstructing the roads. The Corporation is to be at liberty to supply the electrical energy for the routes.

A new arrangement has been come to between the Mansfield Corporation and the Mansfield & District Light Railways Co., under which the latter will be supplied with electrical energy at 1½d. per unit for the first 400,000 units per annum, and 1d. per unit for all further supply, whether for traction, light, or any other purpose. The previous contract was at the rate of 1½d. for the first 200,000 units, 1½d. for the next 200,000 units, and 1d. afterwards.

It was stated at the annual meeting of the Lisbon Electric Tramways last week that, having come to an arrangement with the Lisbon municipality as to the interpretation of certain clauses in the Company's concessions, a new municipal body was elected before this arrangement could be ratified, and, unfortunately for the Company, the newly-elected Council will not endorse what its predecessors have done. The whole work of negotiation, therefore, has to be started over again.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

It is stated that wireless telephonic communication has been established between Nauen (Germany) and Pola (Austria), a distance of rather more than 580 miles. It is interesting to note that the Gross Glockner group of mountains is in the direct line between the two stations.

The Cefndu Transatlantic wireless station, near Carnarvon, which will be the largest transmitting station in the world, will be formally opened in a few weeks. It will communicate direct with a station close to New York. There are ten steel masts, each 400 ft. high, and the last row of masts is about 1,400 ft. above sea-level. The plant at this station will be controlled and operated from the receiving station at Towyn, Merionethshire.

A speed of 100 words a minute has been attained in wireless transmission between Chelmsford and Letterfrack, in Galway. Wireless stations are now being established at Stonehaven (Kincardineshire) and Newcastle-on-Tyne to supplement the existing overhead lines.

It is proposed to construct a new central exchange in Swansea in substitution for the two existing exchanges now working. The Telephone Department is spending some £200,000 on the telephone development of the district.

Private messages in code or cipher are again accepted for all offices in Mexico *via* Galveston, excepting Vera Cruz, in which case messages must be written in plain English, Spanish, or French. Either class of message is only accepted at sender's risk.—Telegraphic communication with Dawson, Yukon, is interrupted, and telegrams are forwarded by best means at sender's risk.

## "Prana" Lattice Armouring

in steel, copper, brass or phosphor-bronze.

☛ For the protection of Rubber Hose, Flexible Tubing, Cables, &c., &c.

☛ Neat in appearance, extremely flexible, rust-resisting. Low cost.

☛ Especially adapted to the protection of "Sud" connections.

"Prana" Die Castings

are ready for assembling.

☛ The dies in which they are cast are virtually a gauge, so that further examination is unnecessary.

☛ They cannot vary.

☛ Made from alloys of guaranteed soundness.

☛ British owned and made—"Tough and True."

Let us send you particulars and samples.

"PRANA" DIE CASTINGS.

AERATORS LTD. (INC.) UPPER EDMONTON, LONDON, N.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

### QUESTION No. 1,391.

If there is a rise in frequency in a system owing to speeding up of the generator, the watt-hour meters are caused to run slow. What is the explanation of this, and what is the relation between the change of frequency and the slowing down of the meters?

(Replies must be received not later than first post, May 28th.)

### ANSWERS TO No. 1,390.

What is the "heating time-constant" of a transformer? How can it be calculated from the design? Is it affected by alterations of load or the method of cooling?—J. H. B.

The first award (10s.) is made to "A. G. R." for the following reply:—

When a load is first applied to a transformer there will be very little heat radiated, so that the temperature rises quickly. As the heating proceeds the transformer begins to give out heat through convection, conduction, and radiation, with the result that the temperature increases at a less rate than before. For a given load the temperature will ultimately attain a steady value, this condition being reached when the

rate of generation of heat is equal to the rate of cooling. The steady temperature to which any part will rise depends on the losses, extent and nature of the cooling surfaces provided, and the facilities afforded for cooling. When the heated body is perfectly homogeneous and the cooling at its surfaces uniform, the curve of temperature rise is an exponential, the ultimate temperature being approached asymptotically.

If  $T_r^\circ$  = maximum or final temperature rise  $^\circ\text{C}$ .

$T_t^\circ$  = temperature rise at the end of any time  $t$  (sec.).

$e = 2.718$  = base of the Napierian logarithms.

$$T_t^\circ = T_r^\circ [1 - e^{-t/T}]$$

where  $T$  is the time constant of the equation, and is the time in which the total mass would reach the final temperature if there were no loss of heat by conduction, convection, and radiation. This latter condition is shown on the diagram by the tangent to the curve at the origin, and time taken to reach the final temperature would be  $T$ .

If  $\alpha$  = slope of this tangent to the time axis, then

$$\frac{T_r^\circ}{T} = \tan \alpha$$

Hence, at the commencement of heating the slope of the temperature curve is dependent only on the heat generated and the thermal capacity of the body. It follows from this latter equation, therefore, that

$$\frac{T}{T_r^\circ} = \frac{\text{Heat capacity of body}}{\text{Heat generated in body}}$$

and when a constant final temperature is reached, all the heating losses are dissipated, and the final temperature rise is

$$T_r^\circ = \frac{\text{Heat generated}}{\text{Cooling surface}} \times \text{a constant}$$

$$= \frac{K \times \text{Watts lost}}{\text{Cooling surface}} = \left[ \frac{KW}{A} \right]^\circ \text{Centigrade.}$$

where  $K$  is the temperature rise per watt per square foot if  $A$  = cooling surface in sq. feet.  
 $W$  = watts to be dissipated.

The following table gives the values of  $K$  for different methods of cooling, and these values may be taken as representative of modern practice.

Values of  $K$  = Temperature Rise per Watt per Square Foot.

Nature of cooling surface.	Oil-cooled.	Air-cooled.		
		Natural draught.	Air-blast 2.65 cubic feet per second per K.V.A.	Air-blast 5.3 cubic feet per second per K.V.A.
Coils { d.c.c. Round wire...	0.22	1.72	1.07	0.65
{ d.c.c. Square wire...	0.22	1.50	0.91	0.54
{ Bare strip .....	0.18	1.29	0.75	0.43
Iron edge surface .....	0.18	0.70	0.32	0.22
Oil to air through case ...	1.61	—	—	—
Oil to cooling water .....	0.25	—	—	—

If the load alters, the loss in watts dissipated will also alter, and thus temperature rise will change.

It may be pointed out that after a time  $4T$ , i.e.,  $4 \times$  time-constant, the temperature is within about 2 per cent. of its theoretical final value, and may therefore be regarded as constant.

The second award (5s.) is given to "W. C. G. H.," who writes as follows:—

The time constant of a transformer is a measure of the time in which the transformer would reach its final working temperature, if no heat was lost by radiation and conduction. It is therefore proportional to the heat capacity of the materials of which the transformer is constructed, and inversely proportional to the cooling surface. The constant is used in practice in the determination of the temperature rise of transformer after a working period less than that taken to attain maximum temperature, by formula

$$T_1 = T(1 - e^{-t/T})$$

where  $T_1$  = temperature rise after prescribed interval of working.

$T$  = Maximum temperature rise.

$e$  = Base of Napierian logarithms (2.7183).

$t$  = Time of working interval in seconds.

$k$  = Time constant of transformer.

In designing, the constant is obtained by dividing the joules required to raise the mean temperature of transformer  $1^\circ\text{C}$ . (a), by the watts lost by radiation, &c., of transformer for  $1^\circ\text{C}$ . rise above surroundings (d).

$$a = (\text{kilograms iron} \times h + \text{kg. copper} \times h_c) \times 1.3 \times 4.2 \times 1000.$$

$h$  and  $h_c$  are the values of specific heat for iron and copper (11 and .09 respectively).

1.3 = ratio mean internal to external temperature (approx.).

4.2 = ratio of calories to joules.

1000 gives results for kilograms.

$d$  is obtained by dividing the effective cooling surface (which consists of the area of windings exposed to the cooling medium, + edges only of core iron) by a constant  $C$  depending on the cooling system and thickness of insulation on windings. Designing constants should be obtained experimentally for special cooling systems, but following table gives approximate values. Cooling surface in square decimetres.

Natural draught (perforated case)—14.

Air blast (average draught)—8.

Oil filled—2.

The latter constant is very low and can only be reached when the cooling oil is itself cooled by water circulating through it. Without the latter the radiation of heat from the oil tank must be similarly calculated.

With specially high voltages constants are slightly higher owing to the bad heat conduction of the insulation.

The above shows that the time constant decreases as methods of cooling improve. Changes of load do not affect it, the transformer reaching its maximum temperature for any constant proportion of its full load, in the same time as taken to attain full load maximum temperature on full load, the resultant final temperature alone varying with the load.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published May 14th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in *italics* indicate communicators of inventions from abroad.

4,071/13. **Automatic Telephone System.** D. S. HULFISH. This specification describes a method by which one conductor can be used, both for the operation of the clutch of a distant switch, and as a test conductor for determining whether the distant switch is in normal position or not. Provision is also made whereby, in the case where similar circuits having a common destination are used, these duplicated units are used in rotation so that if one call fails owing to a fault in one particular circuit, on repetition of the call, the next unit of apparatus is utilised. The latter is accomplished by causing each unit to test "busy" after it has been used for a call, so that the following call is sent through the next unit. When the last unit of the group has been used, this "false busy" condition is removed from all the circuits, which may then be made use of again. Seventeen figures.

6,911/13. **Manufacture of Tungsten.** O. VOIGTLÄNDER. A mixture consisting of 60 per cent. tungsten tri-oxide and 40 per cent. aluminium is placed in a crucible and burnt in a strongly heated furnace. A current of inert gas is passed through the crucible during the process. Pure, homogeneous tungsten is obtained.

29,203/13. **Ventilation of A.C. Motors.** SIEMENS BROS. and E. O. KIEFFER. Air for rotor cooling is drawn through axial ducts by a fan in usual manner, and issues out through a vent pipe immediately. Air for stator cooling is drawn in by another fan and enters the machine at the end at which the rotor-cooling air leaves it. The two streams of air flowing in opposite directions keep the machine at nearly equal temperatures throughout its length. Two figures.

2,850/14. **Electrolytic Meter.** B.T.-H. (*G.E. Co., U.S.A.*). The anode of mercury is contained in the upper part of the glass body of the meter, and rests on a diaphragm of goldbeater's skin. The cathode is of platinum, and is situated beneath the diaphragm. The deposited mercury falls to the bottom of the meter, which is in the form of a graduated tube. Two figures.

## Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** HUGHES [Raising mechanism] 10,188/13; DEUTSCHE GASLUHLICHT AKT.-GES. [Vapour lamps] 15,046/13.

**Distributing Systems, Cables and Wires, &c.:** A.E.G. [Automatic phase regulator] 10,609/13; B.T.-H. (*G.E. Co., U.S.A.*) [Distribution systems for vapour lamps] 19,022/13.

**Dynamos, Motors, and Transformers:** ROLFE [Dynamo excitation] 24,898/12; THOMAS & THOMAS TRANSMISSION, LTD. [Dynamo for accumulator charging] 7,252/13; SIEMENS SCHUCKERTWERKE GES. [A.C. commutator motors] 11,313/13; WEISS [Oil transformers] 24,162/13; SIEMENS BROS. (*Siemens Schuckertwerke Ges.*) [Rectifier] 29,763/13.

**Electrometallurgy and Electrochemistry:** ROCKEY and ELDRIDGE [Copper refining] 7,409/13; SOC. GEN. DES NITRURES [Manufacture of aluminium nitride] 23,740/13.

**Heating and Cooking:** BROADBENT and DAVIES [Heating process] 9,105/13; RAILING and KRAUSE [Soldering iron] 10,500/13; LACASSE [Radiators] 16,485/13; MADSEN [Toaster] 24,419/13.

**Ignition:** HILL (*Apparate-Bauanstalt Fischer Ges.*) [Magnetoe apparatus] 21,509/13.

**Incandescent Lamps:** TAYLOR and WILLIS [Anti-vibrators] 23,388/13; LOEWENSTEIN [Lamps] 2,843/14.

**Instruments and Meters:** CARDEN [High-frequency apparatus] 15,283/13; MELLERSH-JACKSON (*Packard*) [Thermometers] 23,720/13.

**Storage Batteries:** LEITNER [Charging apparatus] 12,639/13; PORDES [Packing enclosure for battery cells] 106/14.

**Switchgear, Fuses, and Fittings:** SCOTT and DEATS [Contacts] 2,169/13; MANSELL [Regulating device] 9,447/13; BLOXAM (*R. Bosch*) [Automatic regulator] 9,959/13; COUSANS [Motor controller] 10,770/13; HODGSON [Distant control switches] 15,642/13; DONOVAN [Fuses] 23,035/13; CHAPMAN and KENNEY [Connection plugs] 25,675/13; LEACH and JOEL [Switch springs] 26,150/13.

**Telephony and Telegraphy:** KATZ [Automatic telephony] 2,302/13; HAUXWELL [Engine-room telegraph] 18,138/13; JUDG, DAVIES, and EASTERN TELEGRAPH CO. [Telegraphy] 5,037/14, 5,831/13; POLLAK [Interrupters] 5,070/14.

**Traction:** NORTON [Tail lights] 16,084/13; DELMEZ [Mounting of tram motors] 17,005/13.

**Miscellaneous:** WATKINS [Electric horn] 10,190/13; BAKER and McKECHNIE [Relays] 11,751/13; FRIED. KRUPP AKT. GES. GRUSONWERK [Separators] 24,355/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Arc Lamps:** SIEMENS SCHUCKERTWERKE GES., 9,960/14.

**Dynamos, Motors, and Transformers:** SOC. ANON. DES AUTOMOBILES DELAUNAY-BELLEVILLE [Dynamo and motor control] 2,437/14; MASCHINENFABRIK OERLIKON [Safety device for motors] 9,542/14.

**Electrometallurgy and Chemistry:** GES. FÜR ELEKTRO OSMOSE [Colloidal process] 10,083/14.

**Incandescent Lamps:** VERON [Pocket lamp] 9,768/14; SEIFERT [Manufacture of tungsten wire] 9,772/14; HELLER [Lamps] 10,387/14.

**Instruments and Meters:** GRISSON [Instrument for measuring Röntgen rays] 8,146/14.

**Telegraphy and Telephony:** AKT.-GES. ELEKTRISK BUREAU [Automatic telephone systems] 9,822/14; BETULANDER [Automatic and semi-automatic telephone systems] 9,840/14.

The following Amended Specifications may now be obtained:—

**Incandescent Lamps:** WOLFRAM LAMPEN AKT.-GES. [Filament supports] 12,753/13.

## Restoration of Lapsed Patents

15,544/09, Electrically-controlled crane brakes, 15,681/09, Improved switches, and 15,682/09, Collecting brushes. Orders have been made restoring these Patents to BERTRAM THOMAS and EUSTACE THOMAS on the 6th day of May, 1914.

## Opposition to Grant of Patent

6,900/13. **Safety device for D.C. instruments.** H. DORMER. Opposition to grant of this Patent has been entered.

## Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

9,331 of May 21st, 1900. **Electrolytic Bleaching.** M. HAAS. A method of ensuring constant circulation of electrolyte used in the production of bleaching liquor. The electrolysis chamber is divided into a number of compartments with inlet holes at the bottom. This chamber is supported in a larger vessel, which is filled with electrolyte. When electrolysis begins, the hydrogen evolved rises to the surface, and so causes an upward current in each compartment. Fresh liquor enters at the bottom to replace that which overflows into the storage vessel.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** C. O. BASTIAN and A. E. SALISBURY [Mercury vapour lamp] 1,995/03; M. VON RECKLINGHAUSEN [Mercury vapour lamp] 2,495/04.

**Distributing Systems, Insulating Materials, &c.:** B.T.-H. (*G.E. Co., U.S.A.*) [Insulating material] 2,127/09, 2,128/09.

**Electrochemistry and Electrometallurgy:** HALL [Production of pure alumina from bauxite by a two-stage smelting process] 2,260/02.

**Heating and Cooking:** W. OTTO [Heating resistance for air baths] 1,922/09.

**Ignition:** O. J. and A. M. LODGE [Ignition apparatus in which the spark gap is connected with a condenser circuit] 2,162/03.

**Instruments and Meters:** J. FERGUSON and KELVIN & JAMES WHITE [Clock mechanism for recording instruments] 2,353/02.

**Storage Batteries:** H. F. JOEL [Method of ensuring circulation of electrolyte] 2,652/07.

**Telephony and Telegraphy:** A. W. SHARMAN [System of leakage telephony] 2,169/09.

**Traction:** PFATISCHER [Motor-driven vehicles fitted with rotary transformers] 2,329/06.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 288. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**DRY BATTERIES.**—A revised edition of a catalogue of "Blue Bell" dry cells for telephone and bell purposes is to hand from the Western Electric Co., Ltd. (North Woolwich). Leclanché and other wet cells are also dealt with to a certain extent. Any of our readers will be supplied with a copy on request.

**SWITCHES AND WALL PLUGS.**—A leaflet from A. Reyrolle & Co., Ltd., gives notice of reductions in prices of quick make and break oil switches, and reductions in prices of glands used in connection with the Reyrolle standard earthed plugs and sockets are announced in another new illustrated pamphlet.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**THE E.C. JOURNAL.**—The latest issue of this little magazine of the Electrical Co. contains some interesting details of the factory wherein the high-tension apparatus sold by them is made. There were also some views of the A.E.G. cable works, some particulars of illumination material, recording instruments, and other specialities, and a list of dynamos and motors in stock.

**ELECTRIC COOKING.**—A neat little folder is being issued by the Westminster Electric Supply Corporation, entitled, "Some Electric Kitchens, and what the Cooks think of Electric Cooking." Over twenty photographs of actual cooking installations are reproduced, and the opinions quoted indicate very satisfactory experience.

**MEASURING INSTRUMENTS.**—We have received from J. H. Holmes & Co. (Newcastle-on-Tyne) a pamphlet describing their various types of ammeters and voltmeters, the "Castle" portable testing set, and a combined form of galvanometer and battery.

**ELECTRIC LIGHTING AND COOKING.**—We have received copies of several new publications which are being issued by the Electric Supply Publicity Committee. An attractive new design has been prepared for an electric cooking poster showing a very up-to-date young lady examining the progress of the cooking of some appetising dish. This is also reproduced as a post-card. Another item is a reprint of a lecture by Mr. F. S. Grogan on "The Cooking Problem: Why Electricity is Winning." Two leaflets addressed to industrial consumers call attention to the advantages of electricity in the laundry and hairdressing business, and a coloured folder sings the praises of the electric iron for domestic purposes.

### NEW INSTALLATION ACCESSORIES

**A** MONG several new accessories just added to the permanent lines carried by the General Electric Co., Ltd. 67 Queen Victoria Street, E.C.), is the neat pattern of suspension switch for through wiring, shown in Figs. 1 and 2. This should prove exceedingly convenient where flexible wire is used, and it is desired to have a means of controlling a circuit close to the apparatus itself other than the ordinary key switch holder. This switch is only 2½ in. long and

FIG. 1.—SUSPENSION SWITCH ARRANGED FOR THROUGH WIRING.

2½ in. in diameter. The terminals are arranged conveniently at each end, an efficient cord grip is provided, and the body is usually composed of best non-inflammable imitation ivory; by short-circuiting the lower terminals with a piece of copper wire, it can be used as an ordinary suspension switch. Other novelties are combined switches and wall plugs, with the firm's well-known "Slick" tumbler movement, a "Slick" two-way flush switch and the special type of bayonet lamp-holder for use with signs, radiators, &c., shown in Fig. 3.

The difficulties of wiring in these positions are lightened by its use, as the back of the lamp-holder is quite open. A substantial backplate lamp-holder known as the "Excel" has also been introduced, having a deep recess at the back

FIG. 2.—SUSPENSION SWITCH WITH ONE PAIR OF TERMINALS SHORT-CIRCUITED.

for the wires. The Company have also brought out some new patterns of externally-insulated lamp-holders, so as to prevent the most careless of workmen from accidentally receiving a shock. Instead, however, of the insulation being of china,

FIG. 3.—LAMP-HOLDER FOR SIGNS, RADIATORS, &c.

buyers now have the option of purchasing these lamp-holders from the General Electric Co., Ltd., fitted, to comply with the Home Office requirements, with outer cases of a special grade of insulating and fireproof composition.

### ARC-LAMP LOWERING GEAR

**A** NEW pattern of arc-lamp contact suspension apparatus has been brought out by the London Electric Firm (George Street, Croydon). In order to give the requisite high degree of insulation both the body and plug are mounted

FIG. 1.—HIGH-TENSION LAMP SUSPENSION APPARATUS.

FIG. 2.—WIRE-ROPE PROTECTOR.

on special corrugated porcelain insulators. The suspension feature is the well-known and tried one, embodying two ratchets in circular form, one superimposed above the other

and set at an angle from it. Every alternate tooth in the lower ratchet is cut away first to allow the pins to enter and trap the plug, the second cycle releasing them and allowing it to pass out. To engage the gear, the winch line is drawn up, and the pins, or horns, on the plunger engage with the ratchet and travel up the inclined face of the upper half until it can be drawn no further, then the winch is slightly reversed, when gravity brings the pins straight down, where it is trapped in the ratchet. To lower, the winch line is hauled again until the pin reaches a dead stop, and a second reversal of the winch lowers the plug with its lamp clear to the ground for trimming. By the use of this device the wire rope is only used for hauling and lowering the lamp, and not for suspending it, and there are no levers or other such contrivances liable to require adjusting. In addition to their well-known self-sustaining winch, the Company has evolved a quicker operating pattern to meet the modern high-speed conditions of trimming 80/100 lamps per day, which practically fulfils the condition of "dropping the lamp," and at the same time possesses the valuable feature of self-sustaining both in raising and lowering, without ratchets, pawls, springs, brakes, or triggers, and assures the safety of the lamp under all conditions whether the handle slips or breaks, or the winch becomes otherwise interrupted in operation. Fig. 2 shows an improved wire rope protector. This is sufficiently flexible to go round the swan neck or other restricted part of an arc-lamp column, and effectually overcomes the old trouble of chafed cables inside the lamp pillar, as the rope works in what is practically a closed conduit throughout its length.

### A TELEPHONE CATALOGUE

A FINE new catalogue of telephone apparatus has been produced by the Western Electric Co., Ltd. (North Woolwich, E.), covering an enormous range of telephone material, from the little domestic set for bell circuits and direct-acting sets for short lines to the latest refinements of automatic exchange equipment, and including many new up-

FIG. 1.—ALL-METAL  
C.B. WALL SET.

FIG. 2.—NEW C.B. DESK SET.

to-date designs. Many patterns of central battery interphones are listed. Among the series of wall sets we notice a number of patterns which have been specially designed for tropical use where protection from ants is desirable. These, as well as other sets, are fitted with the "capsule" closed type of transmitter. Mining telephones are well represented, as well as special instruments for tramway, police and military. A new design of all-metal C.B. wall set is shown in Fig. 1, and a new C.B. desk set in Fig. 2. It will be noticed that

a hand combination set is used in the latter, and that instead of a switch hook being provided, the switch is inside the handle of the instrument, and is actuated by the suspension ring. A great number of cordless and other private branch exchange boards are included; one of the latter is illustrated in Fig. 3. Interesting illustrations are given in the list of exchange manual switchboards, clerks' desks, &c., of various patterns, and other items of exchange equipment, and the section on accessories dealing with batteries, bells, cables, terminals, fuses, heat coils, magnetos, jacks, &c., contains

FIG. 3.—PRIVATE EXCHANGE  
BOARD.

FIG. 4.—LOADING COIL.

items too numerous to particularise. We may notice, however, in the cable section, the special multiple interphone cables with enamelled wire conductors. Among the receivers are some new patterns for wireless work, and a new "watch" receiver, carefully balanced so that it hangs quite straight. Repeating and retardation coils are now regularly listed, and testing sets and tools occupy several pages, and a comprehensive section is devoted to telephone line material. Some notes on the Western Electric machine switching system for exchanges are included in an appendix, and among miscellaneous illustrations at the end are some fine three-colour representations of the London-Birmingham trunk telephone cable specially constructed for put-in loading coils and phantom circuit working, and an 800-pair subscribers' dry-core paper-insulated cable. Views are also reproduced of the laying of the London-Birmingham and other cables; and Fig. 4 shows the standardised form now taken by loading coils used in conjunction with long lines.

### CHURCH LIGHTING

SPECIAL problems are presented in the lighting of ecclesiastical buildings, and of late increasing attention has

ELECTRIC LIGHTING AT ST. ANNE'S CHURCH, LIVERPOOL.

been paid to the subject, with the result that fine examples of church lighting are now in existence, which form a great

contrast to the crude and insufficient arrangements that formerly sufficed.

An excellent example which has been sent us by the British Thomson-Houston Co. (Mazda House, 77 Upper Thames Street, E.C.) is the lighting of St. Anne's Church, Liverpool; an interior view of which, taken by the light of the ordinary installation, is reproduced here. Concealed lighting is employed, and the illumination is obtained from Mazda lamps in "Mirolux" silvered glass trough reflectors attached vertically to the east side of each of the wooden beams which support the groined roof. These beams extend down the wall about 10 ft. beyond the end of the roof arches, and a battery of three Mirolux reflectors is fixed near the lower end of each beam. The reflectors are disposed at such an angle as to throw the light outwards and forwards into the body of the church, in the direction of the altar. The lighting units are only visible to people who turn round in their seats and deliberately look up at them. Looking towards the altar, on which every reflector is trained, it is impossible to see the units at all. The resulting illumination forms an extraordinary contrast with the old gas lighting, which was from lamps fixed to the pillars, about 8 or 9 ft. from the ground. In this position they created an enormous amount of glare, but the illumination on the pews was quite inadequate. The new lighting was designed to illuminate the *whole* of the interior adequately but glarelessly. The altar is lighted in the same way as the main church, and its illumination is helped considerably by the general lighting, since all the batteries of reflectors are directed towards it. As a result the altar is more intensely lighted than the rest of the church, and is thus given appropriate emphasis.

### A NEW THERMOPILE

SOME interest has been aroused lately by the claims which have been put forward regarding the merits of a new form of thermopile which is now being manufactured by The Walker Shaw Syndicate (28 St. James's Square, S.W.). We were present at a demonstration which was given on Friday last at the offices of the syndicate. The complete thermopile is intended to be built in the form of a horizontal flue, with the hot junctions of the thermo-couples arranged around the inner circumference, so that they are heated by the hot gases which pass through. The cold junctions will form the outside of the flue, and will be cooled by a current of air. A small segment of one of these flues, consisting of ten couples arranged for either series or parallel working, was used for the tests. The "hot junctions" of the couples were capped with electrolytically deposited copper, and, in the present instances, were heated by gas jets. A small thermo-couple and milli-voltmeter were used for taking temperatures of the junctions. The following readings were obtained: Temp. of hot junctions,  $375^{\circ}\text{C}$ .; temp. of cold junctions,  $75^{\circ}\text{C}$ . Voltage per couple on open-circuit, 0.063

SECTION THROUGH THERMO-COLUMN.

volts. The ten couples were joined in parallel, and the circuit closed through a high resistance wire and a shunt ammeter. The current indicated was 40 amperes, whilst at the same time the voltmeter reading was 0.035 volts, giving a total power of 1.4 watts for the ten couples. By using the required number of couples, any desired power can be obtained, providing that sufficient space is available. Judging from the drawings of a 30-watt "thermo-column" which has been constructed, the size of a 1-kw. set would need to be about 2 ft. 6 in. outside diam. by 1 ft. 6 in. inside diam. by 22 ft. long. It will be seen from this that a generating set made up of these thermo-columns would occupy considerably more space than any other type of plant at present used. On the other hand, the running expenses would be greatly reduced, providing that the couples maintain their efficiency under

working conditions. The makers claim to have ensured this by the special construction of the couples. The negative element consists of constantan, a nickel-copper alloy, and the positive is of "Golma" alloy. The junction between the two is made by electrolytically depositing a thick coating of copper over both metals. This ensures a perfect and permanent connection.

### PYRENE FIRE EXTINGUISHERS

WE were allowed, by the courtesy of the Western Electric Co., Ltd. (Norfolk House, London), to witness some interesting tests with "Pyrene" extinguishers last week. These tests, which were conducted on the Aldwych site, demonstrated very clearly the remarkable fire-extinguishing properties of "Pyrene." In all, fourteen different tests were made, in which burning petrol, acetylene, celluloid, carbon-bisulphide, wood-wool and cotton-waste soaked in petrol, coal-tar and petrol, were allowed to become thoroughly ignited, and in every case the flames were effectually and promptly quenched. To give an idea of the time required to extinguish the flames, the following examples may be cited:—A tank 18 in. by 15 in. by 18 in. deep was supported about 4 in. above the ground on bricks, and 2 gallons of petrol were poured in. A tap was then opened in the bottom of the tank, and the petrol was ignited both in the tank and on the ground beneath it. After the petrol had burned for thirty seconds, a jet of "Pyrene" was directed on to the flames, which were subdued in forty-eight and a-half seconds. Shortly after this, half a gallon of carbon bisulphide was poured into a bucket, ignited, and allowed to burn for ten seconds. The resulting conflagration was extinguished in the space of two and a-half seconds.

The "Pyrene," which is a colourless, mobile liquid, is squirted on to the burning materials, when it immediately vaporises and forms a dense white blanket, which smothers the flames by preventing access of air. By way of showing the harmlessness of this liquid, it was sprayed over one of the assistants. After a few minutes, it had completely evaporated, without leaving any trace.

We also received particulars of some previous tests which had been conducted at the St. Marylebone Generating Station. In addition to the tests mentioned above, one of the turbo-generators was connected through a liquid resistance to two steel rails butted together, and an arc was formed by drawing one of the rails away from the other. It was found that an arc of 700 amperes at 480 volts was easily extinguished. Another test showed that "Pyrene" has no harmful effect when played upon the commutator and brushes of a machine, even when the latter is running at its full voltage. The extinguisher, which is illustrated above, is easily manipulated by one man, the standard size being 3 in. diameter by 14 in. long, and weighing 5 lb. when filled with "Pyrene" liquid. We understand that the Western Electric Co., Ltd., are sole agents to the electrical trade.

Sectional View.  
PYRENE FIRE  
EXTINGUISHER.

**Trolley Wire Splicing Sleeves.**—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), has added to its catalogue of traction supplies, prices and description of "Acme" splicing sleeves for splicing trolley wires. With these sleeves a very efficient joint can be made with a minimum expenditure of time and labour. The two ends of the wires to be joined are drawn through the two halves of the sleeve, which is made in best gunmetal and heavily tinned, and the projecting ends of the wire are flattened for a short distance, then by means of a central screw, the two halves of the sleeve are brought together. Holes are provided for filling in with solder if thought desirable.

**Cinematograph Carbons.**—The General Electric Co. inform us that their make of "Kinarco" carbons, which are the only cinematograph carbons of British manufacture, were used on the occasion of Mr. H. G. Ponting's special demonstration of his well-known films taken on the Scott Antarctic expedition at Buckingham Palace before the King and Queen of Denmark.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Bedford.**—Steam and other pipework for generating station. Borough Electrical Engineer. May 28th.

**Belgium.**—Tenders are invited by May 28th for the electric lighting of three sheds at the Canal Dock. Tenders to Burgomaster, Hotel-de-Ville, Antwerp. A copy of the specification may be seen at 73 Basinghall Street, E.C.

**Brierfield.**—The offer of the Nelson Corporation to supply electricity in bulk on a seven years' agreement at 2d. per unit for lighting and 1½d. for power, has been accepted.

**Bury.**—A Local Government Board inquiry was held last week concerning a loan of £62,502 for works and mains extensions. This large expenditure is necessitated mainly by the arrangement to supply the Heywood Corporation and Radcliffe Council with electricity in bulk.

**Cleckheaton.**—2,000 yds. 0.5 concentric cable, and 2,000 yds. three-core pilot cable. Town Clerk. May 23rd.

**Darlington.**—Water-tube boiler and cooling tower for Electricity Department. Town Clerk. June 4th.

**Dundalk.**—An inquiry has been held concerning a loan of £20,000 for extensions to the electrical undertaking, with a view to supplying the Great Northern Railway Co.'s locomotive works. An agreement has been entered into for the supply of 480,000 units at nine-tenths of a penny, and all excess over that amount at seven-tenths of a penny per unit. The minimum yearly bill to be £1,800. There was opposition on the part of the Dundalk Gas Co. on the ground that the scheme was unsound, the argument being put forward that the Belfast Corporation could not supply current for their trams at which the Council were offering to supply the Railway Co. in this case.

**Ellon.**—The Council has finally agreed with Messrs. T. C. Smith & Co. with regard to an electric lighting installation.

**Ireland.**—The Loughrea Electric Power & Lighting Co. invite tenders for a power station consisting of gas engine and suction plant, dynamo, battery, switchboard, overhead lines, and street lamps. Consulting Engineer, L. J. Lawless, 27 Castlewood Avenue, Rathmines, Dublin.

**Leeds.**—Motor-driven induced-draught plant for dealing with 230,000 cub. ft. of gas per min. Manager, Electricity Department. June 10th.

**Leigh (Lancs.).**—An inquiry was held last week concerning a loan of £10,225 for electrical extensions.

**London: Hampstead.**—Tenders are invited for one 1,500-kw. turbo-alternator, condenser, pipework, cooling tower, and tank, by June 11th. (See advertisement.)

**Hackney.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £15,750 for electrical purposes.

**Stepney.**—Three years' supply of ampere-hour meters, demand indicators, and time switches, and one year's supply of arc-lamp carbons. General Manager, June 11th. (See advertisement on another page.)—The Finance Committee of the L.C.C. recommends sanction to a loan of £15,000 for mains.

**Woolwich.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £542 for a sub-station site and spare armature.

**Lurgan.**—The Board of Trade has granted the Council a provisional order.

**Oldham.**—Two 3,000-kw steam turbines, water-tube boilers, feed pump, cooling towers, &c. Borough Electrical Engineer.

**Shanghai.**—H.T. three-phase switchgear for sub-station. Consulting Engineers, Preece, Cardew & Snell, 8 Queen Anne's Gate, Westminster, S.W. May 28th.

**Stockport.**—A loan of £17,650 for electrical extensions is being inquired into.

**Swinton.**—The question of converting the present system to three-phase supply is under consideration. An application is to be made to the Local Government Board for a loan of £1,500 for general extensions.

**Watford.**—A Local Government Board inquiry was held last week concerning a loan of £15,150 for extensions into a number of outlying districts, which were authorised by an Act of Parliament last year.

**Wellington (N.Z.).**—Oil break switches are required in connection with the Lake Coleridge power scheme. Tenders by June 1st. A copy of the specification may be seen at 73 Basinghall Street, E.C., but the time is too short to tender, except for those firms who can instruct their agents in Australia by cable.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Birmingham.**—Rebuilding of Northfield public library. City Engineer, Town Hall.—Extension of parcel office, H.M. Office of Works, London.

**Chorley.**—New council offices.

**Coventry.**—Municipal technical institute.

**Dundee.**—Conversion of school building into town hall. Architects, Messrs. Haxton & Walker, Leven.

**Lancaster.**—Cinematograph theatre. Lancaster Palladium, Ltd.

**London.**—New baths, washhouses, and public library are under consideration by the Deptford Council.

**Middleton.**—New mill. Soudan & Co.

**Nelson.**—Rebuilding of Bankfield Mills after fire.

**Rotherham.**—Shops, offices, and arcade in Main Street. Architect, J. Platts, High Street.

**Sal.**—New school. Architects, Hoy & Sisley, 199 Deansgate, Manchester.

**Southampton.**—New library at Portswood.

**Swansea.**—New school in Middle Row. Clerk, Education Offices, 9 Grove Place.

### Miscellaneous

**Clyde Navigation.**—The Trustees of the Clyde Navigation require a twelve months' supply of electrical stores. General Manager, 16 Robertson Street, Glasgow.

**London: H.M. Office of Works.**—Three years' supply of lift ropes. (See advertisement on another page.)

**Metropolitan Police.**—Tenders are invited for the supply and maintenance of electrical cell calls at police stations and police courts for three years. Receiver, New Scotland Yard. June 3rd. (See advertisement on another page.)

**Port of London Authority.**—Twelve new electric cranes are required for the Tilbury Dock extension, and the installation of electric accumulators has been authorised at a cost not exceeding £5,500.

**Montreal.**—A Montreal merchant is desirous of doing business with makers of electrical and hardware specialities. His name and address may be obtained from the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, E.C.

## TENDERS RECEIVED AND ACCEPTED

**Bedford.**—A contract has been placed with the B.T.H. Co. for a twelve months' supply of type R.H. A.C. meters.

**Bootle.**—A contract for two 500-600-kw. rotary converters has been placed with the B.T.H. Co.

**Edinburgh.**—An order has been placed with Messrs. Chamberlain & Hookham for a twelve months' supply of D.C. meters.

**Kirkcaldy.**—An order has been placed with Messrs. Chamberlain & Hookham for a twelve months' supply of D.C. meters.

**London: G.P.O.**—A contract has been placed with the Edison & Swan United Electric Light Co. for a supply of Royal Ediswan drawn-wire lamps.

**Newcastle-on-Tyne.**—The Trainways Committee has ordered forty Angold magazine flame arc lamps from the G.E.C.

**Sunderland.**—The Corporation has ordered twenty-three Angold magazine flame arc lamps from the G.E.C.—A contract for a twelve months' supply of lamp-holders has been placed with J. H. Tucker & Co.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £65 5s. to £65 15s. (Last week the same.)

**The B.E.A.M.A.**—The Union Electric Co., Ltd. (Park St., S.E.), has decided to resign its membership of the British Electrical and Allied Manufacturers' Association, and accordingly has so notified the Secretary of the Association.

## LOCAL NOTES

**Carlisle:** *Minimum Charge for Lighting Consumers.*—The Electric Lighting Committee has fixed a minimum charge of 30s. per annum for lighting consumers. This action has been decided upon in order to avoid the loss on a number of small consumers who only use a few shillingworths of current during the year.

**Edinburgh:** *Charge for Public Lighting.*—The Gas Committee recently offered to carry out the public lighting with high-pressure gas at £7 per lamp per annum, compared with £9 per lamp per annum charged by the Electric Lighting Committee. Apparently as a consequence of this, the Electric Lighting Committee has requested the Electrical Engineer to report generally on the cost of lighting by electricity all the streets in the city at present not lighted by that means, and also as to the question of the existing price.

**Glasgow:** *Control of Electricity and Tramway Undertakings.*—The question of whether the management of the electricity and tramways undertakings should be placed in the hands of one committee has been discussed, but at a joint meeting of the Electricity and Tramways Committees last week it was agreed that the Pinkston tramway power station should be left, as now, under the control of the Tramways Department, provided that each department can get, by means of the interconnecting cables, whatever supply of energy can be spared from the Pinkston station and the Port Dundas lighting station respectively, should such assistance be required by either of the departments.

**Greenock:** *Starting-up of New Generating Station.*—The new 5,000-kw. Westinghouse-Rateau steam turbo-alternator set was started up last week. This is required in connection with the supply to Port Glasgow.

**Hove:** *Management of Council's Electricity Undertaking.*—In answer to a question in the Council last week, the Chairman of the Electric Light Joint Committee stated that, after considering various offers to lease the electricity undertaking, and rejecting most of them, the Sub-committee appointed for the purpose submitted two, together with the offer of the Brighton Corporation to supply in bulk, to Mr. C. B. Smith, the Hove Electrical Engineer, who was also asked to report as to the desirability of the Corporation retaining the management of the late Company's undertaking in its own hands. After this report had been received, two later offers to lease the undertaking had been received, and the Corporation was awaiting further details of these.

**London:** *Agreements under Electric Supply Act, 1908.*—An arrangement has been come to between the Stepney and Shoreditch Councils for a temporary bulk supply by the former to the latter under Section 3 of the London Electric Supply Act, 1908, for a period of one year, with an extension for a further year at the option of Shoreditch. The energy to be supplied is to be E.H.T. three-phase A.C., at a minimum of 6,000 volts, 50 periods. The Highways Committee of the L.C.C. recommends sanction to the agreement on the ground that it will obviate the extension of a small generating station. Attention is drawn to the fact that under Clause 13 any dispute as to the accuracy of the meters measuring the supply, is to be settled by the Board of Trade, but the Committee recommends that in this case any such dispute should be referred to the Council, and not to the Board of Trade.

**Marylebone:** *Presentation of Electric Vehicle Chassis.*—The Electric Supply Committee has had under consideration the purchase of a 10-cwt. electric vehicle for departmental purposes, but Councillor Duncan Watson has now presented the Department with a chassis capable of carrying a load of 30 cwt., and an expenditure of £80 is to be incurred in fitting the necessary battery, tyres, &c.

**Maidstone:** *The Value of Conferences.*—Discussing the desirability of sending Mr. E. E. Hoadley, the Borough Electrical Engineer, to the I.M.E.A. Conference in June, one of the members of the Electric Lighting Committee last week said that the attendance of Mr. Hoadley at various conferences during the year was worth anything from £50 to £100 to the undertaking, and in some cases even £500 per annum. It was agreed that Mr. Hoadley should attend as usual.

**New Reciprocating Engine Set.**—A new Belliss & Morecom E.C.C. reciprocating engine generating set, which has been installed at a cost of some £6,200, was put into operation last week. At the opening ceremony, Mr. E. E. Hoadley, the Borough Electrical Engineer, referred to the increasing demands for electricity for cooking and heating

purposes, and anticipated an enormous increase if only the Corporation had powers to let on hire or hire-purchase the necessary apparatus. If the municipal boroughs in London could be allowed these powers he failed to see why all municipal authorities outside London should not have similar powers.

**Rotherham:** *Power Load Doubled.*—The annual report of Mr. E. Cross, Borough Electrical Engineer and Tramways Manager, states that although the average cost of coal had increased from 81'9d. to 104d. per ton, the generating costs had decreased from '757d. to '651d. There was an increase of units sold as follows: Tramways, 18'14 per cent.; power, 53'96 per cent.; and lighting, 7'92 per cent. The average price obtained for current was 1'296d., as against 1'416d. last year, and the net profit was increased from £5,179 to £7,358. He recommended that the price of power for the tramways be reduced from 1½d. to 1¼d. per unit.

## APPOINTMENTS AND PERSONAL NOTES

Mr. W. L. Magden has been appointed representative of the London Chamber of Commerce to give evidence before the Royal Commission on Railways.

The Birmingham Electric Supply Committee have appointed Mr. E. A. Mills (North Metropolitan Electric Power Supply Co.) to the post of Assistant Constructional Engineer to the Electric Supply Department, at a commencing salary of £250 per annum, rising to £300. There were 194 applications.

The Stockport Electricity Committee has decided that a Chief Assistant Engineer is necessary in the interest of the undertaking, and recommends that Mr. R. H. Lee, at present Resident Engineer, be appointed to this position, at a commencing salary of £200 per annum.

The following appointments have been made to fill vacancies on the staff of the Nelson Electricity Department:—Mains Superintendent, W. D. Chalmers; Assistant Station Superintendent, H. Whittaker; Shift Engineer, John Crabtree.

The salary of Mr. C. Bexon, Electrical Engineer to the Kilmarnock Corporation, has been increased by £100 per annum.

A switchboard attendant is required in the Blackburn Electricity Department for E.H.T. three-phase, single-phase, and D.C. three-wire lighting and power, together with traction switchboards. Commencing wage 30s., rising to 34s. per week.

A telephone wireman is required with experience in the maintenance of large private telephone exchanges. (See advertisement on another page.)

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &amp;c.

**Callender's Cable & Construction Co.**—At the annual meeting on Thursday, the report and accounts given in our issue for May 7th were adopted. Sir Fortescue Flannery, Bart., M.P., Chairman of the Company, said he did not think that in all the history of the Company there had been a time of greater activity than the years 1912-13, both at home and abroad. A very satisfactory year's trading had been accomplished, and particularly in the case of telephones was the development greatly in advance of any previous year. Especially had the Company been successful in its relations with the General Post Office, whose efforts they were doing their best to second in order to develop the telephone system of the country. Mr. T. O. Callender, the managing director, said that the feature of the past year had been the steady increase of business with the Company's old customers. The only department that had not been altogether satisfactory was the engineering department. The Company had, with many others, been harassed by labour troubles, and especially in the engineering department had these troubles hindered business.

## SUMMARY

At the Annual General Meeting of the Institution of Electrical Engineers last Thursday, interesting statements were made by the Chairman and Vice-Chairman of the Industrial Committee, who, although both members of Council themselves, were in conflict with the Council itself as to the duties which the Committee might properly perform. The limitations imposed by the Council on the scope of the Committee, they explained, had prevented its doing the work which, it had been hoped, could be done. Mr. Robert Hammond, at the same meeting, explained in his most convincing manner that the decrease in membership of the Institution was really an increase. (Page 292.)

An account is given of the remarkable action taken by the Bethnal Green Borough Council in connection with its projected electricity undertaking; Mr. J. F. C. Snell has refused to act for the Council further as Consulting Electrical Engineer. (Page 292.)

An illustration is given of the type of double helical gearing used in geared turbo-generators such as that at the Horseferry Road Station at Westminster. (Page 293.)

SMALL half-watt lamps for low voltages are being introduced in Germany which can be used for automobile head lamps, and in conjunction with small step-down transformers for house lighting. (Page 293.)

We are able to publish an illustration of one of the Diesel engines built for the new Macclesfield Electricity Works. (Page 293.)

THE electric drive of planing machines is dealt with in our Questions and Answers columns. (Page 294.)

SOME Patent specifications published last week deal with phase regulation of alternators connected in parallel, control of winding motors, vapour arc lamps, and oil-cooled transformers. A lapsed Patent relating to conduit fittings has been restored by the Comptroller. Opposition has been entered to a Patent of Crompton & Co. for a system of motor control. Proceedings in Opposition to the grant of a tungsten Patent were heard before the Comptroller last Monday, the opposers being the B.T.-H. Co. and C. Gladitz. (Page 295.)

THE railway from Stockholm to Saltsjöbaden is to be converted to electric traction on the 1200-volt D.-C. system. (Page 296.)

THE year's working of Hull Municipal Telephone system has resulted in a profit of £2,631.—The new Transatlantic wireless station near Carnarvon was inaugurated last week.—The Marconi v. Helsby wireless patent action will be heard on June 23rd. (Page 296.)

OUR Trade Section contains descriptions of a ship-board electric clock installation, an electric floor cleaning machine, a switch panel for 800 volt lighting circuits, an alternating-current buzzer, and illustrates a semi-indirect lighting installation, and some alabaster dishes for this kind of illumination. (Pages 296 and 298.)

TURBO-GENERATORS are required in Dartford and Auckland; expenditures on generating plant are contemplated as follows: Bootle (£19,312); Cleethorpes (£10,000); Falkirk (£5,799); Huddersfield (£21,500); Kettering (£3,000); Leeds (£212,000); Shoreditch (£22,000); Southwark (£10,000); and Redditch (£18,000); rotary converters are required by the L.C.C., and a new storage battery at Horsham. (Page 299.)

A LARGE number of miners' houses have been wired out in Ashington.—A keen fight is being carried out between the Islington Electricity Committee and the Gas Light & Coke Co. with regard to the lighting of the Islington Guardians' buildings.—The "Northumberland" clause will probably after all be inserted in the Kingstown electric lighting order.—The Hackney Electricity Committee recommends certain variations in the proposed tariff for charging electric vehicles. The Barnes Council, on the other hand, has adopted the scheme put forward by the Electric Vehicle Committee in its entirety. (Page 300.)

## ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MAY 28TH.

*Institution of Railway Signal Engineers.*

2.30 p.m. At Institution of Electrical Engineers. "American Signal Practice as Compared with British Practice," by A. H. Rudd.

THURSDAY, JUNE 4TH.

*Institution of Mining Engineers.*

11 a.m. At Burlington House, Piccadilly. "Development of the Internal Combustion Engine for Power Generation at Collieries," by J. Davidson.

*Royal Institution.*

3 p.m. Lecture I., by Prof. S. P. Thompson, F.R.S., on "Faraday and the Foundations of Electrical Engineering."

### The London Electrical Engineers.

Headquarters (46 Regency Street, S.W.) open Sats. till noon. Closed Monday, June 1st, and Tuesday, June 2nd, for Whit-sun holidays. *Rating Exam.* for all Cos. from 7 to 10 p.m. every Wednesday.

(TO-DAY) THURSDAY, MAY 28TH, C. Co. FRIDAY, MAY 29TH, D. Co. THURSDAY, JUNE 4TH, C. Co. FRIDAY, JUNE 5TH, D. Co.

## ANNUAL MEETING OF THE INSTITUTION OF ELECTRICAL ENGINEERS

THE annual meeting of the Institution was held on Thursday. At the commencement a vote of condolence was passed with the family of the late Mr. R. Kaye Gray. The announcement of the election of Members of Council was made as reported in our last issue, and the Council's Report was presented.

*The Decrease in Membership.*—In answer to a question by Mr. F. C. Raphael (Editor of ELECTRICAL ENGINEERING), Mr. Robert Hammond, as Chairman of the Membership Committee, said it was true that there had been a decrease of 39, which on the face of it might appear to be a calamity, but when the position was analysed this was far from being the case. The membership was now 508 more than it was two years ago. The comparison must not be made simply with the previous year, for there had then been a large number of new members joining to get in before the higher subscriptions for new members came in force.

*The Council Ballot.*—The President, in answer to another question by Mr. Raphael, said he did not believe the fact that the ballot papers having been sent out with the proceedings had any appreciable effect on the number of papers returned. As a matter of fact, 23 per cent. were returned this year, which was a larger percentage than last year, when the ballot papers were sent out in separate envelopes. Nevertheless it was proposed that in future the ballot papers should be sent out in separate envelopes.

*Municipal Loans Committee.*—Mr. W. C. P. Tapper, Borough Electrical Engineer, Stepney, speaking with reference to the Municipal Loans Committee mentioned in the report, expressed the hope that the Council would be well represented upon it, as otherwise there was a fear that this Committee would meet the same fate as the Industrial Committee. The President said that already three company engineers and three municipal electrical engineers had been appointed on this Committee.

*Model General Conditions.*—Mr. Tapper also asked whether the Model General Conditions had received the approval of the B.E.A.M.A. and of the I.M.E.A.

The President said that neither the B.E.A.M.A. nor the I.M.E.A. had formally adopted the Model General Conditions, but he believed the B.E.A.M.A. was very much in agreement with a great many clauses, and he hoped that the I.M.E.A. also was.

### The Industrial Committee.

Mr. H. Hirst said that, as Chairman of the Industrial Committee, he would like to say a few words in order to prevent any misunderstanding in the minds of the members. The Council had considered it essential that the Industrial Committee should not deal with matters which might be construed as having a political bearing. The Members of Council on the Committee were anxious to respect this wish, but when it was considered that there were 400 municipal electrical stations in the country, it would be difficult to find subjects connected with electricity supply which did not have something of a political nature about them. The Council had other wishes which did not appear in the constitution of the Committee. They considered that the Committee should not touch upon questions which might be to the detriment of a certain section of its members, and some members of the Committee were anxious to respect this wish, but others were not, because when it was a matter of benefit to the whole industry it might be thought one section might have to give way a little for the general good. As the Council had made this ruling, however, it was difficult for the Industrial Committee to choose suitable subjects which were likely to meet with the approval of the Council. Other members of the Council thought that the In-

stitution would suffer in prestige if it lent its name to discussions dealing with money matters, such as finance or trade discounts that were likely to enter into the discussion of industrial questions. It was due to him as Chairman of the Committee, and also to some of the members, to say that the above were some of the limitations of the constitution which had not been referred to in the report, and which acted against the possibility of the Industrial Committee doing such work as it was hoped could have been done.

Later on in the proceedings, Mr. A. H. Seabrook said that as Vice-Chairman of the defunct Industrial Committee, he regretted that the Institution could not see its way to become the centre of the industry in commercial and industrial matters as well as in technical matters. All members of the industry were dependent upon £ s. d., and whether their interests were scientific or technical, the question of finance and commercial matters was of essential importance not only for the existence of the Institution as a whole, but for the individual members. It was regrettable that the Articles of Association did not permit of the Council taking its full share in these industrial and commercial matters. It was evident by the attendance at the meeting, and the complacent attitude shown that the members were perfectly satisfied, unlike himself, with the Institution which confined itself to those matters for which it was originally constituted. He was not making these remarks by way of complaint, but merely by way of regret.

Mr. K. Edgumbe said he would like to say "Amen" to Mr. Seabrook's remarks.

Mr. W. W. Mordey said he would like to say a few words on the other side, because he believed that the interests of the Institution could be best maintained by following an example always before them, and giving attention to the foundations of electrical engineering—the scientific and technical foundations—rather than attempting in any way to lower the dignity of the Institution by making it a trade association.

This was all the discussion on the report, which was then unanimously adopted.

### The Tothill Estate.

#### Suffragettes and Socialists as short-period tenants.

Arising out of the Treasurer's statement, Mr. Raphael asked for some explanation why the net revenue from the Tothill estate was only £302, which amounted to about 1½ per cent. of the capital outlay upon it. Mr. Robert Hammond, the Honorary Treasurer, said that the reason for this was that the Council had felt it to be the best policy not to encourage seven, fourteen, or twenty-one years' tenancies, so that if a favourable offer came into the market, the property could be sold out quickly. This had resulted in its being impossible to obtain the full rental value of the premises, as people would not take them up on the short leases. Since the accounts were published, however, the "suffragettes" had made a favourable offer for some of the premises, and at the Council meeting that afternoon, the Fabian Society—whether it was cause and effect he did not know—had offered to pay £250 a year rent for another part of it, so that the revenue from the Tothill estate for the coming year would be the highest value yet obtained, namely, £886 as against £550 in previous years.

The usual votes of thanks to the Council and honorary officers, with the re-election of the latter, closed the proceedings.

## HOW NOT TO TREAT A CONSULTANT

MR. J. F. C. SNELL, who was acting as Consulting Engineer to the Bethnal Green Borough Council, has been treated in a remarkable manner, which has resulted in his refusing to act for the Council any further. It will be remembered that, on Mr. Snell's recommendation, arrangements are being made for a supply of electricity in the district, taking current in bulk from the neighbouring Stepney Borough Council, and an agreement has actually been made with the Borough Council for a supply. The Electricity Committee recommended that Mr. Snell be appointed to carry out the scheme adopted, at a fee of 5 per cent. of the capital expenditure. This was not carried in the Council, however, and the Committee were instructed to advertise for a consulting electrical engineer to proceed with the scheme. The Association of Consulting Engineers then took the matter up, and informed the Committee that it was against the rules of professional etiquette for any consulting engineer to reply to advertisements, and the Committee therefore again submitted their recommendation that Mr. Snell be appointed, as above. After a long and heated discussion this was carried, whereupon a letter sent by Mr. Snell (who did not know that the Association of Engineers had done anything in the matter) declining to act further in connection with the matter was somewhat belatedly read. This letter was referred to the Electricity Committee, who again approached Mr. Snell and informed him of the official resolution appointing him. Mr. Snell has, however, refused to reconsider his decision.

## A GEARED TURBO-GENERATOR

IN last week's *ELECTRICAL ENGINEERING* (p. 279) an illustrated description was given of the 1,500-kw. continuous-current generator driven at 300 r.p.m. through 10 to 1 gearing by a steam turbine running at 3,000 r.p.m. We are now able, through the courtesy of Messrs. C. A. Parsons & Co., the makers of the turbine and gearing, to reproduce a photograph of a similar gear-case open, which shows the nature of the gearing very well. As already pointed out, this gearing is on the same general lines as the Parsons' marine gearing, consisting of two wide helical gear rings with the slope in opposite directions to balance the end thrust. The

REDUCTION GEARING FOR STEAM TURBINE.

pinion is solid steel, and the gear-wheel consists of a cast-iron drum, over which are shrunk and keyed the two mild steel rings, each 15 in. wide and about 6 ft. in diameter, in which the teeth are cut. The gear is lubricated by oil squirted continuously at the line of contact of the teeth. A flexible coupling is provided between the turbine and the pinion shaft, but the armature of the generator is coupled rigidly to the gear-wheel shaft. In some other makes of turbine gearing floating bearings are used for the pinion shaft, enabling it to take up its own position, but Messrs. Parsons do not find this necessary, and, in accordance with their usual practice, have fitted solid bearings.

## SMALL LOW VOLTAGE HALF-WATT LAMPS

IN addition to the great progress being made with half-watt lamps for ordinary supply voltages and large candle-powers, several new sizes of which are already on the market in Germany, and may be expected before long to be ready for sale in this country, attention of manufacturers has been devoted to the manufacture of units of small candle-power of equally low specific energy consumption. These, however, are so far only practicable at quite low voltages, but there is a special field where there is no disadvantage, namely, for automobile lighting. In Germany, the *Auergesellschaft* are already advertising Osram "half-watt" lamps for motor-car headlights with short thick drawn-wire filaments in the 32, 50, 75 and 100 (hefner) candle-power sizes for 6 and 8 volts, and 50, 75, and 100 c.p. for 10 and 12 volts. It was the ordinary metal-filament lamp which made electric headlights possible, but the introduction of half-watt lamps will materially reduce the size and cost of the batteries or lighting sets required, besides increasing the economy of working to a point competing easily with acetylene.

For ordinary illumination purposes, small half-watt lamps have also been introduced in Germany, used in conjunction with small step-down transformers, and these transformers are standardised in sizes of 10, 25, and 75 watts, with a secondary pressure of 14 volts, and for 450 and 750 watts with a secondary voltage of 60. The smaller sizes for single lamps are extremely compact, and fit in like adaptors between the lamp-holder and the lamp, while others are combined with a lamp-holder. The gain in efficiency of the lamp over that of the ordinary metal-filament lamp much more than compensates for the loss in the transformer.

In reference to the interview with Herr Rathenau, published in the *Berliner Tageblatt*, and referred to in our issue of May 14th, the *Elektrotechnische Zeitschrift* states that the 25 c.p. and 50 c.p. half-watt lamps referred to as shortly being on the market are A.E.G. ("Nitra") lamps of low voltage, only suitable for use in series, or for supply through low-voltage transformers. These are now being advertised in Germany by the A.E.G. Co. in sizes down to 50 c.p.

**Iron and Steel Institute.**—The autumn meeting of the Iron and Steel Institute will be held in Paris from September 17th to 22nd.

## DIESEL ENGINES AT MACCLESFIELD

WE referred in *ELECTRICAL ENGINEERING*, April 30th, p. 248, to the opening of the new station for the supply of Macclesfield, and through the kindness of Messrs. Hick, Hargreaves & Co. we are now able to illustrate one of the two Diesel engines of their manufacture which form part of the equipment. These are each of the three-crank vertical type, with cylinders 16 in. diameter by 19 in. stroke, running at 250 r.p.m. They are of the enclosed forced-lubrication type and their general appearance is seen in the photograph of one of them erected on the manufacturers' test bed. Although Messrs. Hick, Hargreaves & Co. have only taken up the manufacture of Diesel engines comparatively recently, this is not the first that they have supplied for electrical purposes, and another example that may be men-

250-H.P. DIESEL ENGINE FOR MACCLESFIELD.

tioned is a 500-B.H.P. three-crank engine supplied to the Guildford Electricity Supply Co. The Company's designs follow in many respects what may now be regarded as practically standard practice, based on accumulated experience, but in comparison with other makes they claim that their engines are particularly substantial and are designed to stand up for long periods under full load without giving trouble. The bearing surfaces throughout are very large, and the lubrication is carefully attended to. The aim has been to make a thoroughly sound and reliable engineering job throughout.

**Proposed Housing of Engineering Societies in Manchester.**—A conference of representatives of Engineering and Technological Societies in Manchester was held on May 1st to consider the possibility of establishing a common headquarters for the various societies and institutions which hold meetings in Manchester. Sir Thomas Holland was in the chair. Resolutions were adopted in favour of such a scheme of co-operation, and the following gentlemen were invited to form a provisional Organising Committee:—Mr. W. T. Anderson (convener), Mr. C. Pilkington, and Sir T. H. Holland (Manchester Geological and Mining Society), Mr. J. A. F. Aspinall (Institutions of Civil and of Mechanical Engineers), Mr. E. J. Christian (Junior Institution of Engineers), Mr. R. H. Clayton (Society of Chemical Industry), Mr. H. L. Foster (Association of Mining Electrical Engineers), Mr. E. G. Hiller and Dr. E. Hopkinson (Manchester Association of Engineers), Mr. R. Matthews (Institution of Mechanical Engineers), Mr. F. R. McConnell (Textile Institute), Mr. J. G. Newbigging (Institution of Gas Engineers), Mr. S. L. Pearce (Institution of Civil Engineers), Dr. E. Rosenberg and Mr. E. D. Simon (Institution of Electrical Engineers), Mr. J. H. Stubbs (Manchester Engineers' Club), and Mr. W. H. Whitby (Engineering Employers). This committee is to ascertain the views of the Councils of the respective societies and to prepare a scheme.

**Meter Approved.**—The Board of Trade has approved the Ferranti Polyphase Watt-Hour Meter Type C.T., and the means for fixing same.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,393.

In house-wiring installations consisting only of plain pendants, compare the relative advantages and disadvantages of: (1) looping-in in the ordinary way both at the ceiling roses and switches, or (2) using 3-plate ceiling roses and looping-in only at the ceiling roses.

(Replies must be received not later than first post, Monday, June 8th.)

### ANSWERS TO No. 1,391.

A 20-h.p. shunt-wound motor running at 510 r.p.m. has been put in to drive the main shafting of a machine shop at 120 r.p.m. The rated full load current is 75.5 amperes at 220 volts. When the planing machine is in action this current is not exceeded on the cutting stroke, but rises to 120 amperes on the return stroke. Will some reader suggest a remedy? Would it be practicable to alter the gear ratio between the motor and shafting, and to increase the speed of the motor by weakening its field?—"ELECTRIC MOTOR DRIVE."

The first award (10s.) is made to "W. H." for the following reply:—

Dealing first of all with the solution propounded by the querist, it would appear difficult to find a reason for speeding-up the motor, but possibly the idea is to utilise the extra rotational energy stored in the moving parts of the motor at the higher speed to help the motor at the moment the planer reverses. The gain would not, however, be very great, owing to the small radius of gyration of the moving parts, and there would be considerably increased sparking, due to the higher speed and weaker field. As this is obviously a reversible belt-driven planer, the best and cheapest method would be to fit a heavy flywheel-pulley in place of the planer-pulley driven from the shop shafting. Assuming this to be approximately 3 ft. in diameter, a weight of about 5 cwt. to 6 cwt. concentrated in the rim of the pulley would probably reduce the kick of current to a reasonable value. The reason for this is that during the cutting stroke the power taken by the planer is less than at any other period. The resulting tendency to speed-up stores energy in the flywheel, and this stored energy is delivered during the moment of reversal, and to a small extent during the high-speed return stroke. The result being, of course, a slowing-up of the flywheel. This should considerably reduce the variations in load on the motor, and a further improvement could be effected by adding a few series turns wound cumulatively on the motor fields. The effect of the series turns being to produce a slightly increased speed-drop between no-load and full-load, thus utilising the stored energy of the flywheel to a greater extent. In case a flywheel pulley could not be fitted, a flywheel of similar dimensions should be fitted to the same shaft. It is now the practice with first-class makers to compound slightly D.C. motors for this class of work.

The second award (5s.) is given to "ASTATIC," who says:—

"Electric Motor Drive" is experiencing the usual conditions which exist when shunt-wound motors are used to drive planing tables. The power taken when the tool is cutting is nothing when compared with the power required to reverse the machine and return the table to the cutting position again. Planing

tables in some cases weigh many tons, and as the rate of return is nearly twice the cutting rate, it will be seen that an additional amount of power is required. The motors driving these machines should have sufficient surplus of power to meet the sudden reversal and increase of speed, otherwise considerable sparking will take place, which heats the commutator, so that eventually it will be impossible to keep it free from flats, and the mica will always be standing above the segments.

"Astatic" then suggests fitting a smaller pulley on the shafting which drives the planer countershaft to decrease the speed of the machine; tightening the belts which are worked by the striking gear, and overhauling the motor bearings to see if they are worn, so that the armature is in an unsymmetrical field. He then makes the following proposal for compound winding:—Remove the armature and place the yoke of the motor on a bench, so that it is easy to get at the field coils. Then obtain about twenty-five yards of circular annealed copper wire, double cotton covered, No. 1, S.W.G. This wire will carry about 80 amperes without heating. Wind upon each shunt field coil about ten turns of this wire in the following manner. Cut a number of pieces of vulcanite  $\frac{1}{4}$  in. thick, eight pieces for each pole, as shown in Fig. 1, and fasten them to the pole piece

Fig. 1.

Fig. 2.

with tape, as shown in Fig. 2. Then cut some strips of mica to the size of the grooved portion of the vulcanite, sufficiently long to extend the whole length of the coil. Place the mica in the groove at the back, bottom, and top, and wind the copper wire on the "former" thus made.

When ten turns have been placed on each coil there will be a space between the new coil and the shunt coil. This will enable you to tape the coil up with linen tape, after which it should be well varnished with shellac varnish.

If the new coil should be a little slack it may be tightened by inserting a few small ash wedges between the back of the new coil and the front of the field coil. The coils should then be connected up in series with each other, and the whole placed in series with the armature. We have now converted the shunt machine into a compound machine at a very small cost, and there is no doubt that it will do its work in a satisfactory manner.

He concludes:—What we have done electrically is this. When the planing table is reversed, and the table is returning quickly to the cutting position, the additional current will traverse the new series turns and the field strength will be much greater. The result is that the speed will be decreased a little, but the field distortion and armature reaction will be considerably decreased, and it will be found that the motor will not be taking much more than the full-load current. If there is a slight increase in the current it will not be detrimental to the efficient working of the motor, as it will be intermittent, and there will be no sparking at the brushes, but it may be necessary to move the brushes in a forward direction, as the neutral position will be altered.

Care must be taken to see that the series turns are wound in the same direction as the shunt turns, and that the armature current is traversing these turns in the same direction as the shunt current.

**London Electricity Supply.**—At Tuesday's meeting of the London County Council, the Finance Committee recommended that loans by several Borough Councils for electricity supply purposes be sanctioned. This was opposed by Mr. O. Lewis, who had also a motion on the agenda instructing the Council's Electricity Supply Committee to report further in three months. It was pointed out, however, that any scheme of the Council's could not be approved by Parliament before next session, that it would take three or four years to erect a power station, and that in the meantime the Borough Council electricity undertakings must discharge their statutory obligations to supply new consumers.

**List of Supply Stations.**—A very conveniently arranged booklet containing tables of particulars of electric supply undertakings, tramways, and railways, and electric power companies has been issued at the price of 1s. net by Messrs. H. Alabaster, Gatehouse & Co. (4 Ludgate Hill, E.C.), which, if not quite as complete as some existing lists, is in the most convenient form of any that we have seen.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published May 21st, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

10,609/13. **Phase Regulation of A.C. Machines.** A. E. G. This specification describes a method of automatic maintenance of phase equality between alternators connected in parallel. Any known type of phase-responsive instruments may be employed. The phase difference between the equalising current flowing from one alternator to the other, and the main current of one of the alternators, is utilised to operate the instrument, which in turn can be made to alter the excitation of the alternator in question, so as to correct the phase inequality between the two machines. Twelve figures.

11,313/13. **Control of A.C. Commutating Motors.** SIEMENS SCHUCKERTWERKE GES. This invention applies particularly to winding motors. The control is effected by a lever which determines the position of the brushes relative to the neutral position. An auxiliary lever is provided by which the connections of the stator can be altered for either backward or forward running. For braking, the control lever is moved so as to bring the brushes to the other side of the neutral position, thus causing the motor to supply current to the mains. Braking resistances are at the same time switched into the circuit. The control lever and the auxiliary lever are connected through linkwork, so that the braking resistances cannot be switched in until the brushes have passed the neutral point. Five figures.

15,046/13. **Vapour Arc Lamps.** DEUTSCHE GASÖHLICHT AKT.-GMS. The body of the lamp is filled with a gas which, during the operation of the lamp, is driven out of the arc chamber, by the vaporised mercury, into either a special cooling chamber, or into the atmosphere. In the latter case the gas used is air; in the former, neon or argon can be used. The outlet from the arc chamber must be long enough to prevent the escape of the mercury vapour. To start the lamp, the mercury is caused to boil either by external heating or by tilting the lamp so as to short-circuit the anodes. Three figures.

24,162/13. **Oil-cooled Transformers.** H. WEISS. To prevent the deleterious effects which are due to the presence of air above the surface of the oil, this specification describes a means by which the transformer case can be completely filled with oil. An outlet pipe communicates with a vertical cylinder in which a weighted piston works. When the oil expands, the piston rises. The weight of the piston serves to maintain a pressure in the transformer casing, which effectively prevents the cooling liquid from leaking into it through the material of the cooling coils. Three figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Names in italics indicate communicators of inventions from abroad.**

**Distributing Systems, Cables and Wires, &c.:** B. I. & H. C. and MORDEY, ASTLEY & SAUNDERSON [Conductors and supports] 7,805/13; HODGSON [Wiring] 15,643/13; WESTERN ELECTRIC CO. (*Woodward*) [Insulated conductors] 26,684/13.

**Dynamos, Motors and Transformers:** A.E.G. [Dynamo-electric machines] 7,784/13, 10,608/13; B.T.-H. and TAYLOR [Dynamo-electric machines] 10,919/13; B.T.-H. (*G.E. Co., U.S.A.*) [High-frequency generators] 11,240/13.

**Electrometallurgy and Electrochemistry:** WATTMANN and TUDOR ACCUMULATOR CO. [Welding of rails] 11,847/13; ELLIS (*Sodium Process Co.*) [Furnace] 29,418/13.

**Ignition:** LONGFORD & CLARK [Spark plug] 7,365/13, 19,838/13; KETTERING and CHRYST [Ignition system] 6,074/14.

**Incandescent Lamps:** B.T.-H. (*G.E. Co., U.S.A.*) 10,918/13; JOHANN KREMENEZKY [Manufacture of metallic filament lamps] 19,838/13; PORDES [Portable lamps] 3,992/14.

**Instruments and Meters:** RYAN and BROWN [Earthing device for testing purposes] 10,987/13; KELVIN & JAMES WHITE, LTD., and KING & ALEXANDER [Mariners' compass] 11,158/13; EVERSHED & VIGNOLES and CLARK & SENIOR [Contacts] 15,968/13; STEPHENSON [Voltmeter] 21,143/13; HOTHAM and WILSON [Recording instruments] 91/14.

**Storage Batteries:** SABLON [Accumulators] 16,684/13.

**Switchgear, Fuses and Fittings:** RAILING and GARRARD [Motor control] 10,416/13; PACE and KELUM [Switches for signalling systems] 10,717/13; BLOXAM (*R. Bosch*) [Regulators] 25,046/13; CUMONT [Motor control] 27,988/13; HITZELBERGER and NEW BRITISH EVER-READY CO. [Switches] 970/14.

**Telephony and Telegraphy:** RADIO SIGNAL CO., SHEPARD and MCKECHNIE [Aerial or submarine wireless systems] 3,103/13; JOHNSON [Telephone system] 10,864/13; MARCONI'S WIRELESS

TELEGRAPH CO. and RYAN [Wireless telegraphy] 11,106/13; LEIMBACH [Wireless telegraphy] 5,535/14.

**Traction:** HUNT (*Gresham*) [Insulated railway van] 28,963/13.

**Miscellaneous:** RALPH [Gas detector for hand lamps] 5,568/13; KNABE, GREENWALD and FARMAN [Horns] 10,396/13; FORSTER [Magnetic coupling] 13,308/13; BEY [Advertising device] 15,348/13; KEMP & LAURITZEN [Relays] 29,448/13; BUCKY [Röntgen ray appliance] 7,788/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Arc Lamps:** STEINMANN [Mercury vapour lamps] 10,523/14.

**Dynamos, Motors and Transformers:** SIEMENS SCHUCKERTWERKE GES. [Rotary transformers] 10,493/14; LA COUR [Converter] 10,562/14.

**Electrometallurgy and Chemistry:** DEUTSCHE GOLD UND SILBERSCHEIDE ANSTALT VORM. ROSSLER [Electrolytic preparation of metals] 10,193/14.

**Ignition:** R. BOSCH [Engine starters] 560/14.

**Incandescent Lamps:** SCHMIDT [Pocket lamps] 8,353/14.

**Instruments and Meters:** SIEMENS & HALSKE AKT. GES. [Time recorders] 10,477/14.

### Proceedings in Opposition. May 25th, 1914

13,282/12. **Manufacture of Ductile Masses of Tungsten, &c.** P. SCHWARZKOPF, S. BURGTALLER, and WOLFRAM LABORATORIUM DR. ING. P. SCHWARZKOPF. The specification, of which an abstract was given in our issue of October 9th, 1913, page 572, relates to the preparation of ductile tungsten by a process of pressing and sintering, from oxygen containing powders of the metal. The claim was opposed by two parties, viz., C. Gladitz and the B.T.-H. Co. The former based his opposition upon the fact that the process described by the above specification requires that when sintering is complete, the pressure must be relieved on three sides of the mould simultaneously by any of the known methods. It was contended that C. Gladitz's Patent No. 12,244 of 1912 anticipated this. The Comptroller pointed out that if the applicants infringed upon this patent in carrying out their process, there was the usual remedy. He could not, however, allow the opposition upon this point. The B.T.-H. Co. then submitted that (1) no new invention was disclosed in the specification; (2) the method of carrying out the process was not properly described. The applicants claimed novelty in the production and use of a *fine-grained* powder of high density, whereas Specification No. 8,031, of 1910, which was cited by the B.T.-H. Co., requires the use of a *comparatively coarse-grained* powder of high density. It was suggested that the "fine grain" of the applicants' specification was identical with the "comparatively coarse grain" of the previous specification. Novelty was also claimed in that the process described in the specification yields tungsten metal having in solution a small percentage (0.1 to 5 per cent.) of oxygen. The B.T.-H. Co. claimed that this is practically what results from the process described by Specification No. 4,644 of 1908. In support of the second ground of opposition, the opponents refer to that part of the specification which states that the pressure of the hydrogen which is used for reducing must be less than the partial pressure of oxygen when the latter is combined to form the lowest oxide of tungsten. Expert evidence was brought to show that this pressure cannot be ascertained by any known means, so that the specification was impracticable. The Comptroller reserved his decision upon the two latter points.

### Restoration of Lapsed Patents

9,537/08. **Junction boxes for metallic conduits.** An Order has been made restoring this Patent to C. VAUGHAN and C. BIRCH on the 11th of May, 1914.

### Opposition to Grant of Patents

6,806/13. **Motor-control for regenerative systems.** CROMPTON & CO., LTD. Opposition to this Patent has been entered.  
19,345/12. **Dynamo for lighting vehicles.** S. L. PRICE. The Comptroller has decided to allow the grant of this Patent.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, &c.:** B.T.-H. and E. B. WEDMORE [Circuit-breaker for A.C. systems] 3,192/09.

**Dynamos, Motors and Transformers:** J. BRKE [Dynamo windings for three-wire distribution] 21,584/07.

**Electrochemistry and Electrometallurgy:** AKT. GES. BROWN, BOVERI, ET CIE [Nickel-iron alloy for turbine blades] 27,217/09.

**Storage Batteries:** P. MARINO [Accumulator plates] 2,683/09.

**Switchgear, Fuses and Fittings:** J. BELCHER [Tumbler switch] 3,130/09.

**Miscellaneous:** W. SCHRÖDER [Electric clocks] 2,596/09.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

A report has been submitted by the Hull Corporation Telephones Committee dealing with the work of the Department for the year to March 31st. The gross profit amounts to £6,270, an increase of £416 on the previous year, and after meeting capital charges there is a surplus of £2,631. The Manager reports that it has been possible to link up the additional subscribers of the late Post Office system without adding to the exchange or underground plant. In moving the adoption of the report, the Chairman of the Committee expressed the opinion that if such a statement had been made some years ago the telephone systems throughout the country would by now have been in the hands of the municipalities.

The completion of the Cefndu wireless transmitting station near Carnarvon, referred to last week, was celebrated on Wednesday of last week by a dinner given at Carnarvon to Mr. Marconi. The station, which takes power from the North Wales Power Co., is to communicate direct with a station yet to be completed at New Jersey, and works in conjunction with the receiving station at Towyn, from which it is controlled. Communication is at present carried on with Glace Bay. In addition to the regular transmitting equipment, special experimental apparatus is installed in connection with Mr. Marconi's latest continuous-wave system.

A new record in long-distance wireless telegraphy has recently been established. The Pacific mail liner *Mongolia*, during a journey between the Orient and San Francisco, is reported to have succeeded in exchanging messages with Boston, U.S.A., when at a distance of 8,500 miles.

It is announced that a combine is about to take place between the German Telefunken and Goldschmidt Cos., who own the patents of the Arco and Goldschmidt high-frequency machines respectively.

A meeting of the National Telephone Co. will be held at Hamilton House, Temple Avenue, E.C., on June 25th, at 12 noon, to hear the liquidator's account of the winding-up.

The hearing of the patent infringement action between

Marconi's Wireless Telegraph Co. and the Helsby Wireless Telegraph Co. has been fixed definitely for June 23rd.

On the 22nd inst communication with Dawson City was restored.—As from the 26th inst. the Companies whose routes go *via* Madeira are charging half rates for deferred telegrams to Bolivia, and they must be written in plain Spanish, English, French, Latin, or Italian.

## ELECTRIC TRACTION NOTES

The railway from Stockholm to the charming waterside resort of Saltsjöbaden (about ten miles in length), which, although of standard gauge, is a self-contained line, unconnected with the main Swedish railway system, is to be converted to electric traction on the 1,200-volt continuous-current system. A half-hourly service is to be run instead of the present hourly service, and trains composed of one motor car, in the centre, and one to six trailers, each to carry seventy-five passengers are proposed. Each motor-car will be provided with four motors, each rated at 110 kw. on the one-hour rating, coupled permanently in pairs of two in series. Control will be by field variation. The contactors will be worked from a 65-volt circuit also used for lighting obtained from a motor-generator and a stand-by battery. The trains will be heated by a number of 3-kw. heaters in series on the power circuit, and their control switch will be actuated by the controller, so that they are only in circuit when the motors are not under current. A contact thermometer will only permit of their circuit being closed when the temperature is below a certain value. The controllers are arranged to cut current off, and to apply the brakes the driver releases his hold on the handle. The equipment will be supplied by the Allmänna Svenska Elektriske Aktiebolaget of Västerås.

The British Electric Traction Co. is able to place £50,000 to reserve as the result of its working for 1913, compared with £40,000 in the previous twelve months, to declare the dividend on the 6 per cent. cumulative preference stock, and 3½ per cent. dividend on the 7 per cent. non-cumulative preference stock.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 299. —

### ELECTRIC CLOCKS ON THE "AQUITANIA"

A COMPLETE installation of "Pulsynetic" electric impulse clocks has been fitted throughout the *Aquitania*. These clocks were manufactured by Gent & Co., Ltd. (Leicester), with whom the order was placed through Edward & Sons (92 Buchanan Street, Glasgow), their Scottish agents, and the installation was carried out under their supervision by W. C. Martin & Co. A very large number of dials are fitted, of various designs and finishes, and hardly two are alike. Several of them are old masterpieces of the horological art, which have been fitted with "Pulsynetic" movements, while

MASTER CLOCK ON THE "AQUITANIA."

the original dials and hands were retained. Notable among such instances is an old verge bracket clock fitted in the drawing-room. The master clock, or impulse transmitter, is placed in the chart room, and is fitted with a chronometer

balance. A novel and ingenious automatic advancing and retarding mechanism fitted to the master clock enables all the dials to be simultaneously corrected to ship's time daily. We understand that the principle of automatically advancing is an entirely new contrivance, and supersedes the existing cruder methods of advancing the ship's clocks when sailing eastwards. The firm has issued a special booklet on "Electric Clocks for Ship Use," of which our readers are invited to apply for copies.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**ELECTRIC IRONS.**—A leaflet from Drake & Gorham describes the "Triangle" pattern of electric flat iron.

**FITTINGS AND ACCESSORIES.**—Among new leaflets which have recently been issued by the Sun Electrical Co. (118 and 120 Charing Cross Road), are descriptions of a convenient ceiling rose combined with a switch actuated by pulling a chain, and some new fittings for half-watt lamps, both for interior and exterior lighting.

**BELL INDICATORS.**—We have received from the Sterling Telephone & Electric Co., Ltd. (210-212 Tottenham Court Road, London), a pamphlet giving particulars and sizes of their new electric bell indicators, which are made suitable for from two to thirty indicators.

**IRONS AND DOMESTIC APPLIANCES.**—In connection with their scheme for introducing the various domestic uses of electricity to consumers by means of free trials of electric irons, referred to in another column, the General Electric Co., Ltd., have issued a neat little 32-page booklet entitled "Electricity in the Home," and an idea of the cost thereof. A long range of G.E.C. heating specialties, with which our readers are already familiar, are described in well-chosen words.

### ROTARY FLOOR MACHINE

WE reproduce herewith an illustration of an electrically-driven floor machine made by The Electric Floor Machine Co., Ltd. (118 City Road, London, E.C.). It consists of a circular brush, which is rotated by a small electric motor through gearing. Several different types of brush are supplied with each machine, which can thus be used for a variety of purposes, including scrubbing, waxing, and polishing, for wooden floors, or grinding and dressing for stone or marble. The motor, which is rated at  $\frac{1}{3}$  h.p., is controlled by a switch

ROTARY FLOOR MACHINE.

conveniently situated on the handle of the machine, current being obtained either from a wall-plug or lamp socket. The saving in time and labour which is effected by the use of this machine is considerable. In cases where the amount of work to be done would not warrant the purchase of one of these machines, the manufacturers are prepared to quote for carrying out the work required.

### 800-VOLT LIGHTING CIRCUITS

A NEW arrangement of panel, as specially constructed by A. Reyrolle & Co. (Hebburn-on-Tyne), for use in power and sub-stations on South American railways, is shown in the accompanying figure. The marble front is

800-VOLT LIGHTING PANEL.

mounted on a box-shaped frame carried on a pair of wall brackets. A change-over switch, operated from the handle shown on the bottom of the marble panel, enables the lighting supply to be taken from one or other of two sources.

### ALL OTHERS BOW BEFORE *The* **'CRYSELCO'** METAL FILAMENT LAMP

The lid of the main fuse is so interlocked with this change-over switch that access to the terminals can only be obtained when the switch is in the "off" position, as shown on the photograph. There are four lighting circuits leading away from the top of the panel through quick-acting rotary switches in porcelain covers and fuses. The latter are of a cartridge type, provided with handles for the purpose of easy removal. The arrangement is for taking a direct-current 800-volt lighting supply from the track circuits, one pole being earthed.

### AN ALTERNATING CURRENT BUZZER

THE neat little piece of apparatus illustrated here has been brought out by the London and Rugby Engineering Co., Ltd. (10 Bush Lane, Cannon Street, E.C.), and is designed to replace both battery bells and bells supplied from alternating circuits through separate transformers. It can be used

A.G. BUZZER.

on all ordinary A.C. supply voltages, and is easily fitted and connected to any existing bell installation. The primary winding, which is connected to the supply is quite separate from the secondary, which is connected to the push circuit. There are no working parts to get out of order, nor to require adjustment.

### ARCADE LIGHTING

THE illustration which has been reproduced here has been sent us by Siemens Bros. Dynamo Works, Ltd. (Tyssen Street, Dalston), and shows the lighting of the new Station Arcade recently opened at Ilford. This contains a number of shop windows, and is situated in the main shopping thoroughfares of Ilford. It links up the High Road with the Station Road, and is illuminated by 100 candle-power Wotan lamp units and Siemens Albalux semi-indirect fittings. The

LIGHTING AT STATION ARCADE, ILFORD.

photograph was taken by the aid of these units only, and it will be observed that the goods displayed can be seen to advantage, even without the aid of inside lighting. The fittings are artistic in appearance, and by the correct arrangement of clear and opal glass, "glare" is eliminated without much actual loss of efficiency. A booklet dealing with Albalux fittings will be supplied to any bona fide trade reader on receipt of inquiry.

**G.E.C. Novelties.**—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), advise us that among new lines of apparatus which they are introducing is a particularly light and handy form of grinding, polishing, or buffing motor equipment weighing only 5½ lbs., and some new patterns of switch and fuse sets, including one mounted on a varnished oak board with corner insulators and one in an interlocked iron case.

### ALABASTER DISHES

A VERY large variety of translucent reflector bowls of different materials has been placed on the market from time to time by the British Thomson-Houston Co., and one of the latest developments in this direction is the introduction of a series of real alabaster bowls for this purpose. These are cut from solid blocks of alabaster. The dishes are semi-transparent, and when used in conjunction with Mazda lamps produce a soft, diffused illumination, beautifully mellow in quality. The dishes can be had with a predominating tint

ALABASTER DISHES FOR SEMI-INDIRECT LIGHTING.

of white, red, or yellow. In no case is the colour uniform, because the surface of the alabaster is veined like marble, and there are consequently a number of different shades and colour effects in each dish. There are at present four patterns available, in various diameters suitable for use with the standard forms of semi-indirect lighting fittings. Our readers are invited to inspect these dishes personally at the B.T.H. Co.'s showrooms (Mazda House, 77 Upper Thames Street, E.C.), or to write for a copy of a new price sheet, whereon these articles are illustrated in colours.

**Domestic Uses of Electricity.**—The General Electric Co., Ltd., are conducting a special campaign towards promoting the more general use of electricity for domestic purposes. The particular aim is to obtain an entry for electricity into those houses where electric lighting is in vogue, for heating, cooking, and general power by means of the "Magnet" electric iron. To this end they have made arrangements whereby contractors, stores, and ironmongers can supply "Magnet" domestic electric irons for 15 days' free trial. By payment of 13s. 6d. the "Magnet" iron can be bought, and used as much as the purchaser desires in his own home for a fortnight, and, if at the end of that time complete satisfaction is not obtained, the purchase money will be refunded in full in exchange for the iron.

**The Strength of Metal Filament Lamps.**—A testimonial which has been received by the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex), refers to a batch of 600 lamps in small parcels done up in corrugated paper, which were being conveyed by a motor-cycle side-car along a road in India, and were thrown out when travelling at 20 miles per hour without damage.

**Lamp-locking Devices.**—The "Lamlok" Co. (148 Addison Gardens, W.) inform us that they have now devised an easily operated lock for locking lamps into Benjamin china backplate holders, in response to many inquiries which had been received in that direction.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Auckland.**—Three 750-kw. D.C. mixed-pressure turbo-generators and one 1,500-kw. three-phase turbo-generator with auxiliary plant and sub-station equipment. Messrs. Preece, Cardew & Snell, 8 Queen Anne's Gate, S.W.

**Australia.**—The Melbourne City Council requires 900 yds. 7/16, and 1,600 yds. 7/14 S.W.G. concentric lead-covered cable. Messrs. McIlwraith, McEacharn & Co., Billiter Square Buildings, E.C.

**Bootle.**—A Local Government Board inquiry was held last week concerning a loan of £19,312 for electrical extensions.

**Clacton-on-Sea.**—A twelve months' supply of fittings. Town Clerk, June 3rd.

**Cleethorpes.**—A loan of £10,000 is to be applied for to carry out the extension scheme prepared by Mr. S. Vesey Brown, the consulting engineer.

**Dartford.**—One 500-kw. high-pressure steam turbo-alternator with surface condenser, pumps, air filter, transformer, &c. Borough Electrical Engineer. June 15th.

**Falkirk.**—An expenditure of £4,799 is contemplated upon an additional battery, and £1,000 upon a switchboard.

**Galashiels.**—Messrs. Balfour, Beatty & Co., on behalf of the Galashiels & District Electric Supply Co. has submitted a plan of the route of the proposed cable which it is intended to lay in connection with the electric lighting scheme.

**Horsham.**—The capacity of the storage battery at the generating station is to be doubled, at an estimated cost of £400, with an estimated extra annual maintenance charge of £28 10s.

**Huddersfield.**—The Local Government Board has sanctioned a loan of £21,500 for the purposes of the electricity undertaking.

**Kettering.**—Loans are to be taken up with the Kettering Industrial Co-operative Society to the extent of £1,000 for assisted wiring, £1,400 for mains, and £600 for services, at 3½ per cent.

**Leeds.**—A Local Government Board inquiry was held last week concerning loans amounting to £212,000 for the general purposes of the electricity undertaking. One of the items is £17,600 for the taking over of the Roundhay & District Electric Lighting Co. Mr. C. N. Hefford, Manager of the Department, said that the Roundhay consumers would have their charges reduced to half the present figures if the scheme were sanctioned.

**London: L.C.C.**—Tenders are to be invited for rotary-converters, static transformers, and an overhead crane for the tramway sub-stations.

**Hammersmith.**—An additional main is to be laid in the Goldhawk Road at an estimated cost of £1,153.

**Shoreditch.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £11,073 for mains, house services, and meters, and £11,481 for mains, transformers, and switch-gear.

**Southwark.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £10,087 for machinery, house services, and meters.

**Redditch.**—The Council has decided to adopt the scheme recommended by its consulting engineers, Messrs. Handcock & Dykes, to extend the electricity undertaking, at an estimated cost of £18,000.

**Salford.**—It is anticipated that additional generating plant will be required in the near future.

**Trebizond.**—An electric lighting concession has been granted to Osman Effendi Gurdji Zadé. The *Board of Trade Journal* states that it is probable that he will exercise his option of transferring the concession to another person or company.

### Wiring

**Manchester.**—Electric lighting at the Soss Moss Special School, Warford, Cheshire. Education Offices, June 10th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Harrogate.**—New school.

**Hitchin.**—Technical school. Architect, W. Millard, 10 Gray's Inn Square, W.C.

**Luton.**—New secondary school.

**Portsmouth.**—Elementary school, Wimborne Road. Town Clerk.

**St. Alban's.**—Additions and alterations at County Asylum. Architects, G. T. Hine & Pegg, 35 Parliament Street, S.W.

**Wolverhampton.**—Rebuilding of Theatre Royal.

### Miscellaneous

**Morocco.**—The Government of the French Protectorate in Morocco has been authorised to raise a loan which includes a provision of £440,000 for telegraphs and telephones.

**Spain.**—Two electric 5-ton portal cranes with revolving platforms are required at Huelva. Further particulars at 73 Basinghall Street, E.C.

**Warwick.**—Electric motors, centrifugal pumps, switchgear, automatic control apparatus, &c., for Longbridge pumping station. Consulting Engineers, Messrs. Dodd & Dodd, County Chambers, Corporation Street, Birmingham.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Barnes.**—An order has been placed with the Electrical Apparatus Co. for 100 meters.

**Colwyn Bay.**—An order has been placed with Messrs. Chamberlain & Hookham for meters.

**Dunedin (N.Z.).**—Messrs. Lawrence and Hanson have obtained a contract for three-phase Isaria meters.

**Edinburgh.**—A contract for C.C. meters (Bastian Patents) has been placed with the Electrical Co.

**Glasgow.**—The following are among the successful tenderers for supplies for the Electricity Department for the coming twelve months:—Meters, Chamberlain & Hookham, Ferranti, British Thomson-Houston Co.; flame arc-lamp carbons, W. Webster; ordinary arc-lamp carbons, Sloan Electrical Co.; rubber-covered cables, Craigpark Cable Co.; L.T. mains, Callender's Cable & Construction Co.; E.H.T. mains, W. T. Glover & Co.

**London: L.C.C.**—Eight firms were recently asked to tender for testing plant for polyphase meters. The Highways Committee now reports that only two of the eight firms tendered, and that the prices received were much in excess of the estimate. It is therefore recommended that none of the tenders be accepted.

**Hammersmith.**—The tender of the Armorduct Manufacturing Co. for insulated cable at £92 16s. less 2½ per cent. is recommended for acceptance. Twenty-one tenders were received, the prices ranging from the accepted tender (the lowest) to £172 15s. less 2½ per cent.

**Tunbridge Wells.**—The tender of the B.T.-H. Co. for a turbo-alternator, and that of Isaac Storey & Sons, for condensing plant, have been recommended for acceptance by the Electricity Committee.

## APPOINTMENTS AND PERSONAL NOTES

An assistant telephone engineer and a junior telephone engineer are required by the Constantinople Telephone Co. (See advertisement on another page.)

Mr. C. Bottomley Smith, Engineer to the old Hove Electric Lighting Co., has been transferred to a similar position under the Corporation since the acquisition of the undertaking.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £65 5s. to £65 15s. (Last week the same.)

**Canadian Agency.**—An electrical engineer, with a good connection throughout Canada, wishes to get into touch with United Kingdom electrical and mechanical engineering firms. The name of the inquirer can be obtained at 73 Basinghall Street, E.C.

## LOCAL NOTES

**Ashington: Peculiar Conditions of Gas and Electricity Supply.**—The proceedings on the Bill of the Ashington U.D.C., which sought to set up municipal gasworks, and was passed by a House of Lords Committee last week, revealed some peculiar conditions of the supply of both electricity and gas in the district. The Ashington Coal Co. some forty years ago started a small gasworks, but in 1902 entered into arrangements with the Northern Counties Electricity Supply Co. to supply them with electricity generated on the Coal Co.'s premises, which the Northern Counties Co. was to supply in detail to the district. The greater portion of the houses in the district belong to the Coal Co., and practically all these have been wired for electricity supply, whilst under the agreement between the Coal Co. and the Electricity Supply Co. the former bound itself not to push the sale of gas. The Northern Counties Co., however, did not prosper, and the Newcastle-on-Tyne Electric Supply Co. took the undertaking over. In 1911 the Council desired a fuller supply of gas in the district, but the Coal Co. was unable to give it under the terms of the agreement already mentioned. The result was that the Council promoted a Gas Bill, and has been successful in getting it through Parliament. The question, however, is as to what degree of success can attend this venture in view of the fact already mentioned that at least two-thirds of the houses in the district are already wired, and a further 600 are in course of being wired.

**Ashton-under-Lyne: Electrical Developments.**—In order to meet the demands upon the electricity undertaking, the Corporation has had to carry out an extension scheme costing some £38,000, which includes the installation of two turbo-alternators capable of a combined output of 4,000 kw. These two new sets were started up last week.

**Barnes: Current for Electric Vehicles.**—The Council has adopted the scheme of the Electric Vehicle Committee given on p. 202 of our issue for April 9th.

**I.M.E.A.**—The Borough Electrical Engineer is to attend the I.M.E.A. Convention in June, and will be allowed a first-class railway fare and a guinea a day for expenses.

**Birmingham: Increased Electricity Profits.**—The annual accounts of the Electricity Supply Department are the most satisfactory ever yet presented. The net surplus is nearly £45,000, of which £25,000 has been placed to renewals, and in conjunction with the balance brought forward from the previous year, the sum of £25,000 is transferred to relief of rates.

**Kingstown: Gas Co.'s Keen Opposition.**—Since the Kingstown electric lighting Order was passed by a House of Commons Committee (ELECTRICAL ENGINEERING, May 7th, p. 264, May 14th, p. 276), the Dublin & Alliance Gas Consumers' Co. has been very persistent in its opposition, and has succeeded in getting several Members of Parliament to block the further passage of the Bill on third reading. As we mentioned at the time the Bill was before the Committee, the Gas Co. endeavoured to secure the insertion of the "Northumberland" clause, in the event of the Order being taken over by the Council, and it is now stated that a modification of the "Northumberland" clause has been inserted in the Bill with general approval, and that it will now go through its further stages without opposition. The first period of the revision of prices is to be after the fifth complete financial year.

**Leeds: Electricity Profits.**—There was a net profit of £14,314 upon last year's working of the electricity undertaking, a decrease of £1,193 over the previous twelve months. Arrangements are in hand for the installation of a 1,200 kw. turbo-generator, and an agreement has been made for the purchase of a large quantity of land in South Accommodation Road for the storage of coal. The site is also regarded as a suitable one for the erection of a new power station when necessity arises.

**London: Hackney: Electric Vehicle Charging.**—In connection with the recommendations of the Electric Vehicle Committee (ELECTRICAL ENGINEERING, April 9th, p. 202) the Electricity Committee recommends that for energy supplied to ordinary consumers from a circuit which is used solely for charging the batteries of electric vehicles, and from which the Council reserves the right to cut off the supply between 4 p.m. and 7 p.m. in October, November, December, January, and February, the charge be 1d. per unit, whilst during the hours of 4 and 7 p.m. in these months the charge be 3½d. per unit. In the case of energy sold to garage proprietors who provide the facilities of charging, a rebate of 20 per cent.

on these charges be made in order to allow current to be supplied retail at the above prices.

**Fulham: Street Lighting.**—The Electricity Committee recommends that an expenditure of £271 10s. be authorised upon the conversion of 100 gas lamps along the lines of electricity mains.

**Islington: Guardians and Electric Lighting.**—A Local Government Board inquiry was held at the Guardians' Offices last week, with regard to a loan of £3,600 for an electrical installation at the Guardians institutions and offices. This matter has given rise to considerable controversy as between the Electricity Committee and the Gas Co., who were represented by Mr. A. Colefax, K.C., whilst the case for electricity was supported by Mr. A. Gay, the Borough Electrical Engineer, and Messrs. Handcock & Dykes, the Consulting Engineers. Mr. F. W. Goodenough gave evidence for the Gas Light & Coke Co. The Council has quoted a flat rate of 2d. per unit, and the intention is to enter into an agreement at this price with a minimum of 125,000 units per annum for a period of five years. Mr. A. H. Dykes estimated that the annual cost of lighting would be £852, and put the figure for gas at £1,348. On the other hand, Mr. F. W. Goodenough said that the cost of gas would be £1,035 including maintenance, and repayment of cost of installation in fifteen years, and with a total candle-power of 100,000. Taking electricity at 2d. per unit, he said it would cost £1,536 to provide 100,000 c.p., whilst with maintenance charges, &c., the total figure would be £2,285.

**Nelson: Extension of Area.**—A seven years' agreement has been made for the supply of electricity in Brierfield.

**Saddleworth: Bulk Supply from Oldham.**—The question of giving a supply in this district is under consideration by the Oldham Electricity Committee.

**Stockton: Economy of Bulk Supply.**—The question of whether it would not pay the Council to increase the quantity of current taken from the Cleveland & Durham Power Co., and to reduce the quantity generated itself, has been raised by one or two councillors. This does not seem to meet with general approval, but more may be heard of the matter later.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &amp;c.

**R. Waygood & Co.**—The provisional agreement with the Otis Elevator Co., of New Jersey, under which Messrs. Waygood will acquire the entire interest of that Company in the Otis Elevator Co. of London, with which it will be amalgamated, has been sanctioned at an extraordinary general meeting.

**Lancashire Power Construction Co.**—At the annual meeting of the company last week some strong criticisms were passed upon the action of the Board of Trade in allowing the Bury Corporation to supply the Heywood U.D.C. in bulk. Heywood is in the Lancashire Power Co.'s bulk supply area, and, acting on the advice of Mr. H. Lloyd, K.C., the directors feel they must resist to the fullest extent, not so much as regards the prejudicial effect of the Bury-Heywood agreement, but with a view to preventing a similar thing happening in other parts of the company's area. One effect of the arrangement between Bury and Heywood would be that districts in the power company's area beyond Heywood might be deprived of a supply, since, without the Heywood supply, the cost of mains to reach these other areas would be excessive.

**B.T.H. Co.**—Mr. J. F. Nauheim, presiding at the annual meeting last week, said that although the past year had been a very satisfactory one, the directors thought it the wisest policy to make use of the profit to further strengthen the position in view of the fact that during the year they will again be spending large sums for the completion of buildings now under construction. The accounts given in our issue of May 14th, p. 276, were adopted.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

### SUMMARY

SOME further details as to the standardisation of electric charging plugs, batteries, etc., have been agreed upon by the Electric Vehicle Committee. (Page 302.)

THE electrical equipment of the L. and N.W. Rly. line from Earl's Court to Willesden is described in an illustrated article. (Page 303.)

THE B.E.A.M.A. has adopted the Institution of Electrical Engineers' Model General Conditions of Contracts. (Page 304.)

SIR JOSEPH SWAN, the pioneer of the incandescent lamp, died on Wednesday of last week at the age of eighty-six. (Page 305.)

MR. A. BRUCE ANDERSON, Managing Director of Ferranti, Ltd., was among those who perished in the disaster to the *Empress of Ireland*. (Page 305.)

A PAPER by Mr. A. P. Trotter read at the last meeting of the Illuminating Engineering Society discussed certain definitions of photometric quantities proposed by an American Committee. (Page 305.)

SOME very promising experiments on the production of steel direct from ores in the electric furnace were described in a paper by E. Humbert and A. Hethey read recently before the Iron and Steel Institute. (Page 306.)

A 300-kw. three-phase arc furnace is in use in Toronto for the production of high-quality steel from ore fines. (Page 306.)

A SYSTEM of drying the air for blast furnaces by electrically-driven refrigerators has been introduced with success. (Page 306.)

A SELF-CONTAINED generating plant for supplying lifting magnets in use on steam cranes is described. (Page 307.)

AMONGST the Patent Specifications published in May were some of interest to mining electrical engineers, dealing with safety lamps, winding motors, and a rock drill. Some others relating to the manufacture of tungsten and aluminium nitride and the construction of electric furnaces should be of metallurgical interest. (Page 308.)

PARTICULARS are given in our "Electric Traction Notes" of recent developments in three-phase working on the Italian State Railways. (Page 308.)

A BILL has been introduced giving effect to the wireless recommendations of the International Convention for Safety of Life at Sea. Successful tests of the German Transatlantic stations on the Goldschmidt system are reported. (Page 308.)

THE effect of change of frequency in alternating-current meters is discussed in our Questions and Answers columns. (Page 309.)

SOME of the Patents published last week deal with regulation of A.C. generators, manufacture of half-watt lamps, electrolytic furnaces, and wireless telegraphy. The half-watt lamp patent is the fundamental patent for nitrogen-filled lamps. A patent for an electric furnace expires this week after a life of fourteen years. Opposition to grant of a telephone patent has been entered. (Page 310.)

OUR Trade Section contains descriptions of an electric salvage pump, an electric alarm lock, and a new form of large electric bell. (Page 312.)

NEW plant is required at Stalybridge, Harrogate, Atherton, Wrexham, Sunderland, Colne, Australia, and South Africa; a number of common battery telephone switchboards are required in Australia; electrical stores at Colchester; and tramcars by the L.C.C. and at Darwen. (Page 313.)

RECORD years are reported by a number of municipal electricity departments.—Mr. J. F. C. Snell has been called in to report as to the general condition of the Belfast electricity undertaking.—The Bexhill Council has refused permission to one of its electrical officials to act as a consulting engineer in his private capacity.—A large electric cooking apparatus has been installed at the new Tower dining room, Blackpool. (Page 314.)

## ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 4TH.

*Institution of Mining Engineers.*

- 11 a.m. At Burlington House, Piccadilly. "Development of the Internal Combustion Engine for Power Generation at Collieries," by J. Davidson.

*Royal Institution.*

- 3 p.m. Lecture I., by Prof. S. P. Thompson, F.R.S., on "Faraday and the Foundations of Electrical Engineering."

TUESDAY, JUNE 9TH.

*Institution of Electrical Engineers: Scottish Section.*  
Annual Summer Outing to Arran.

THURSDAY, JUNE 11TH.

*Royal Institution.*

- 3 p.m. Afternoon Lecture II. "Faraday and the Foundations of Electrical Engineering," by Prof. S. P. Thompson, F.R.S.

FRIDAY, JUNE 12TH.

*Physical Society.*

- 8 p.m. At Imperial College of Science, South Kensington, S.W. (1) "A Magnetograph for Measuring Variations in the Horizontal Intensity of the Earth's Magnetic Field," by F. E. Smith. (2) "The Atomic Weight of Copper by Electrolysis," by A. G. Shrimpton. (3) "Note on an Improvement in the Einthoven String Galvanometer," by W. H. Apthorpe.

**The London Electrical Engineers.**

Headquarters (46 Regency Street, S.W.) open Sats. till noon.

*Rating Exam.* for all Cos. from 7 to 10 p.m. every Wednesday.(TO-DAY) THURSDAY, JUNE 4TH, *C. Co.* FRIDAY, JUNE 5TH,*D. Co.* MONDAY, JUNE 8TH, *A Co.* THURSDAY, JUNE 11TH,*C. Co.* FRIDAY, JUNE 12TH, *D. Co.*

SAT., JUNE 15TH. Annual Course of Musketry all Companies, Purfleet. Miniature Range and Technical Instruction each evening.

**Electrically-driven Barges.**—It has been decided to start a service of electrically-driven barges on the River Hudson next autumn. The boats, which will be 276 feet long, beam 40 feet, with a deep-loaded draft of 6 feet, will be fitted with a turbo-generator, which will supply power to three 75 h.p. motors, which will be direct coupled to three propellers. It has been calculated that the cost of carriage with these barges will work out to about 10d. per ton, as against 3s. per ton when steam tug and fleet of barges are used.

## ELECTRIC VEHICLES

At a meeting of the Electric Vehicle Committee held in Birmingham on May 22nd, sample charging plugs, fitted with earth connection contacts, were inspected, and a particular design was selected for standardisation. Further consideration was given to the method of gripping the flexible cable to the plug and the connecting of the earth wire to the plug shell, but final decision in these matters was deferred. As to the position of the plug receptacle on the vehicle, it was decided to recommend that it should be fixed under the driver's seat, preferably with the plug pointing upwards so as to make it impossible for the driver to take his seat without noticing that the charging connection is attached to the vehicle. It was also decided to recommend that the fixed receptacle in the garage, for taking the charging connections, should be placed in an accessible position, preferably horizontal. As to polarity, it was decided that the centre contact of the plug should always be the negative. This is the standard arrangement adopted by the Electric Vehicle Association of America. On the question of battery plates, a communication was read from the Secretary of the B.E.A.M.A. stating that the accumulator manufacturers' section of that Association had decided to recommend for standardisation a plate for electric vehicle batteries having dimensions of 8½ in. x 5½ in., with lug centres 4½ in. It was further reported that the accumulator manufacturers have under consideration standardisation in the sizes of the cells. As to tariffs for charging electric vehicle batteries, the Secretary reported that up to date 51 municipal electric supply undertakings and three company undertakings had agreed to a rate of 1d. per unit or less for "off peak" charging. Some of these undertakings had come into line upon the whole of the Committee's recommendations in regard to tariffs. The Committee decided that they must be in possession of at least £200 for carrying on the work up to the end of next December. Amounts totalling 35 guineas were promised at the meeting, and the Secretary was instructed to approach the principal municipal owned electric supply undertakings and others with a view to obtaining contributions towards such a fund. With reference to the demonstration of electric vehicles which is being arranged to take place at Birmingham on June 16th in connection with the I.M.E.A. Convention, the Secretary reported that five firms were arranging to send one or more vehicles each.

## EXTRACT FROM LETTER RECEIVED BY A FIRM OF MANUFACTURERS:—

"My electrician informs me that whenever he turns the handwheel provided on the dynamo to regulate the pressure, the corrugated copper drum on the shaft catches alight, and he is unable to extinguish it by the ordinary means."

## LONDON AND NORTH-WESTERN RAILWAY ELECTRIFICATION

WE have already referred to the conversion to electric traction of the section of the London and North-Western Railway between Willesden Junction and Earl's Court, and we are now able, through the courtesy of Mr. F. A. Cortez-Leigh (Electrical En-

They were supplied by Messrs. H. J. Skelton & Co., and made by the Cargo Fleet Iron & Steel Co. (Middlesbrough). They are supported on porcelain insulators of the pattern shown in Fig. 1, attached to the sleepers by malleable iron clips. Special anchor insulators, also shown in Fig. 1, are provided at intervals. The insulators have been supplied by Messrs. Doulton & Co. Each rail-joint is bonded by four copper bonds of the flexible strip type, the four bonds together having a sectional area of 1'4 sq. in. The bonds have been supplied by the Forest City Electric Services Supply Co., of Salford. The bonds have solid drop forged heads, and were fixed into the rails by hydraulic pressure. The trailing ramps are of cast-iron, and the leading ramps on the through lines are of forged steel, and in some cases, as on sidings, of special cast-steel. The jumper cables for connecting the several sections of the rails together at cross-overs, &c., are of Messrs. W. T. Henley's Telegraph Works Co.'s make, and are laid solid in bitumenised fibre troughs, and fitted with

FIG. 1.—ORDINARY AND ANCHOR INSULATORS.

gineer to the L. and N.W. Rly.), to give some further details of the equipment of the line which is already working, as well as of the further work in hand on the railway. At present the electric service merely replaces the old steam service, and pending the completion of the company's own power station at Stone-

FIG. 2.—SEALING TERMINALS.

bridge Park, current is obtained from the G.W. and District Railway Companies' sub-stations.

The track equipment is generally similar to that of the District Railway; the track voltage is about 600. The conductor rails are of special low carbon soft steel, weighing 105 lb. per yd., of the following composition:—Carbon, 0'044;

Mr. Cortez-Leigh's patent sealing terminal. This terminal is illustrated in Fig. 2, and forms an effective seal to the insulation of the cable, and at the same time prevents damage to the cables, due to mechanical shocks and vibration. The feeder and sectionalising switch-pillars are also being provided by Messrs. W. T. Henley's Telegraph Works Co.; a photograph of one of these pillars is shown in Fig. 8.

For a start, four three-coach trains—motor-coach, trailer, and control trailer—are being provided by the Metropolitan Railway Carriage, Wagon & Finance Co., but owing to these not being ready, the service was commenced with rolling stock lent by the District Railway. These vehicles will be supplied with end doors and through communication. A plan showing the seating arrangements is given in Fig. 4. The control gear is placed in a steel compartment at the front end of the motor-coach. The motor-cars will have four motors of 240-h.p., each carried on bogie trucks of specially strong design. The control equipment will be of the multiple unit system with automatic features, including a Dead Man's Handle. Automatic quick-acting air-brakes and the usual

FIG. 3.—FEEDER PILLAR.

FIG. 4.—PLAN SHOWING SEATING CAPACITY OF STANDARD 3-CAR TRAIN.

manganese, 0'189; silicon, 0'080; phosphorus, 0'011; sulphur, 0'029; nickel, 0'255 per cent. The volume resistivity of the rails is approximately six-and-a-half times that of copper.

hand-brakes will be provided. Two of the trains are fitted with air compressors of the Westinghouse Co.'s make, and the other two with the Knorr Brake Co.'s rotary slide-valve

# BELLING NEWS

## Our New Boiling Ring

We are glad to say that, after many and various troubles, we are now getting well into swing with these, and can recommend our single heat ring with confidence.

In construction it is quite unique, and its introduction marks probably the most striking advance in the design of white hot electric cooking apparatus of modern times.

We have to particularly thank many engineers who have assisted us by testing and making suggestions in connection with the first 100 odd samples we sent out, as otherwise it would have been impossible for us to so quickly ascertain and put right the weak spots which were found.

## BELLING & CO.

Cooking & Heating Specialists,

EDMONTON, LONDON, N,

compressors. The main electrical equipment for these trains is being supplied by Siemens Bros. Dynamo Works.

The power-house at Stonebridge Park is nearly ready for the machinery, which will include five Westinghouse turbines driving Siemens three-phase 11,000-volt 25-cycle alternators, and B.T.H. high-tension switchgear. The auxiliaries will be driven by alternating-current motors (supplied either from the main generators through step-down transformers, or from a low-tension turbo-generator set used also for lighting, &c.), except the condenser air-pumps, which will be driven by small steam turbines. In the boiler-house there will be twenty Babcock & Wilcox boilers, with drop-link automatic stokers, super-heaters, and Green's economisers. They will be arranged in two rows with a separate chimney stack for each row. Coal- and ash-handling plant will also be supplied by Babcock & Wilcox, and will include two tray-conveyors for bringing the coal from a large coal storage ground at the end of the power-house site, and two bucket conveyors for elevating coal to the top of the boiler-house and conveying it to the bunkers. A pneumatic system is being adopted for dealing with ashes and soot. The site is of sufficient area to allow of the plant capacity being more than duplicated, and the coal storage will accommodate a supply of some 20,000 tons of coal, all of which can be handled mechanically. In addition, a considerable extra quantity can be stored in the immediate vicinity should occasion arise.

The scheme will involve eleven sub-stations, at Bushey, Headstone Lane, Kenton, Willesden Junction, Queen's Park, West End Lane, Chalk Farm, Dalston, Broad Street, South Acton, and one at the power-house. In each sub-station there will be three B.T.H. six-phase rotary converters, nine single-phase static transformers, a large storage battery, and an automatic reversible booster. The converting units are to be .750 kw. and 1,000 kw., with a large overload capacity, the machines being of self-synchronising type. The transformers will be of the British Electric Transformer Co.'s oil-cooled type, and a contract for the high and low tension switchgear (107 H.T. panels and cubicles, and 140 L.T. panels and accessories, involving a cost of between 50 and 60 thousand pounds), has just been let to the British Westinghouse Co. The high-tension cables will be of three-core, paper-insulated, lead covered, and armoured, supplied by the British Insulated & Helsby Cables, Ltd. In the case of trains to be used on the main electric system, the first consignment of motor-cars are being built by the Metropolitan Railway Carriage, Wagon & Finance Company, and the trailers at the London & North Western Railway Co.'s works at Wolverton. The electrical equipment for these trains is being constructed by the Maschinenfabrik Oerlikon, the general scheme being similar to that of the Willesden-Earl's Court stock.

**The I.E.E. General Conditions.**—The text of the Model General Conditions of Contract, issued by the Institution of Electrical Engineers (see *ELECTRICAL ENGINEERING*, May 7th, page 259), was formally adopted by the Council of the B.E.A.M.A. at a meeting held on May 21st; and, as a consequence, will be used by members (in substitution for the Association's Conditions) in connection with tenders to municipalities, district councils, public authorities, and in respect of all publicly advertised contracts where full general conditions are issued.

**Institution of Electrical Engineers.**—The following is the result of the ballot for new members, and the transfer of members from one class to another, at the annual general meeting on May 21st. *Members:* J. Juttke, W. C. Laidler, F. R. McBerty. *Associate Members:* J. Ashworth, J. V. Levett, A. Franks, R. F. Gill, A. T. Hore, H. B. Taylor (Lieut.-Com. R.N.), E. E. Tipper. *Associates:* C. W. von Roemer, F. H. Wilkins, F. W. Willcox, W. R. Day, W. J. Mountain. *Graduates:* J. W. Alexander, W. F. Andrews, L. W. Barsdorf, F. C. Davies, W. Hull, J. A. Lloyd, J. Lythgoe, E. H. Manly, H. F. Rouse, W. L. Shand, W. H. Sherwin, A. S. Tyler, C. H. Woodward, C. F. Bailey, A. C. Bostel, W. R. Dainty, E. C. Ives, R. G. Jones, H. Metcalf, W. S. Sawtell, W. J. Shaw. *Students:* A. E. Crampton, H. M. de Withmann, N. V. Foote, A. Howarth, J. H. J. Lewis, G. Ross-Bain, H. G. Seagrave, A. R. Tabor, C. J. Trutch, C. Germann, F. N. Linstow, E. F. Kill, H. J. Stone, H. S. Tilson, C. Vowell.

*Candidates transferred from Associate Member to Member:* W. G. MacMuldrow, G. S. Thorne, G. F. Allom, P. Cordiner. *From Associate to Associate Member:* E. J. Jennings, J. D. Morgan. *From Graduate to Associate Member:* A. A. Stone, T. J. Nelson. *From Student to Associate Member:* E. Hutchison, E. H. Woodward, A. M. Doig. *From Student to Graduate:* T. J. Hornblower, A. Plowman, J. P. Rowell.

**The Physical Society.**—An excursion to Cambridge has been arranged for June 20th. Visits will be paid to the Cavendish Laboratory at the invitation of Sir J. J. Thomson, F.R.S., and to the works of the Cambridge Scientific Instrument Co.

**Electrical Exhibition at Bradford.**—The British Electrical and Allied Manufacturers' Association has given permission to its members to exhibit at the Electrical Exhibition to be held by the Bradford Corporation from October 6th to 24th of this year.

## OBITUARY

JOSEPH WILSON SWAN.

THE death, on Wednesday of last week, of Sir Joseph Swan, severs a link with the early days of electrical engineering, and removes a leader in electro-chemical research who was a venerable figure in the scientific world. His life was peacefully ended at his residence at Warlingham, Surrey, at the advanced age of eighty-six.

The son of an inventor of marine appliances of considerable ingenuity, Joseph Wilson Swan was a native of Sunderland, and his early training led him into chemical pursuits. He was first an apprentice to a firm of chemists in his native town, and afterwards joined Mr. John Mawson's chemical business, ultimately, in 1860, becoming his partner, as well as his brother-in-law, and the firm assumed the well-known name of Mawson and Swan. He was fascinated by the work of the early pioneers of photography, and his personal chemical researches were soon directed into such channels. His name is well known in connection with his improvements in both collodion and dry plates, as well as in the inception of the bichromatised gelatine processes which form the basis of nearly every photo-mechanical method.

To most of our readers, however, Swan's name is, perhaps, more of a household word in connection with his work on the carbon filament lamp, a subject which had fascinated him since the age of seventeen, when he saw some of the earliest platinum-iridium lamps of Staitte. After considerable experimenting, he succeeded in producing, as early as 1860, lamp filaments from carbonised paper, but it was not till about 1880 that he perfected his lamp with a parchmentised cotton thread filament in a high vacuum produced by a mercury pump. This was in turn superseded by filaments squirted from a cellulose solution, and afterwards carbonised, a process similar to that in use at the present day. About the same time, however, Edison, working independently in America, conceived similar ideas as to the construction of carbon lamps, and, unfortunately, much money was wasted on questions of priority and commercial rivalry. Ultimately, however, in 1883, an amalgamation of the hitherto contending interests took place, and the Edison and Swan United Electric Light Co. was formed, which for many years held the sole rights for the manufacture of carbon filament lamps in this country. Sir Joseph Swan remained a director of this firm until quite recently.

Another branch of electro-chemical research in which Swan distinguished himself was in the manufacture of lead accumulators, in connection with which he took out important patents for the construction of cellular pasted plates. He also worked a good deal at the electro-deposition of metals, and devised a method for drawing wire direct from copper, deposited at a great speed with a very high current density. Various other electro-chemical manufacturing processes claimed his attention, including the manufacture of cyanides from atmospheric nitrogen.

He was one of the really great men in the vanguard of electrical progress, but his ability was recognised in France, where he was made a Chevalier of the Legion of Honour in 1881, sooner than at home. He was elected a Fellow of the Royal Society, in 1894, and received the Society's Hughes medal in 1904, in which year he was knighted. It is interesting to note that, in company with Lord Kelvin and Dr. Henry Wilde, he was an honorary member of the Institution of Electrical Engineers, of which he had been President in 1898. He had also been president of the Faraday Society and of the Society of Chemical Industry. At his funeral on Saturday, the Institution of Electrical Engineers was represented by Prof. G. Carey Foster, F.R.S., Col. R. E. Crompton, C.B., Mr. J. Swinburne, F.R.S. (Past Presidents), Mr. J. E. Kingsbury (member of Council), and Mr. P. F. Rowell (secretary).

A. BRUCE ANDERSON.

The disastrous wreck of the Canadian Pacific liner *Empress of Ireland* in the St. Lawrence River last week leaves the electrical industry the poorer by one of its most capable business men. We refer to Mr. A. B. Anderson, Managing Director of Ferranti, Ltd., who was a passenger by the ill-fated liner, and is not on the list of those saved. Mr. Anderson had been on a business tour in Canada, and was returning home. He was forty-four years of age, and leaves a wife and three sons, the two eldest of whom are at school.

Mr. Anderson joined Mr. S. Z. de Ferranti as accountant in 1892, and remained with the firm during the reconstruction after the removal to Hollinwood in 1897. He gradually rose to be General Manager, and was appointed Managing Director in 1908. He had a strong personality, being a keen business

man and firm of purpose. He was also an ardent Tariff Reformer, and took some interest in political matters in Manchester. Last year, when the firm's head office was moved to London, Mr. Anderson came to live in town permanently. In 1912 he was elected an Associate member of Council of the Institution of Electrical Engineers, and still had another year of office to serve. Another direction in which his energies were directed with great success was in connection with the formation of the British Electrical and Allied Manufacturers' Association. In this he took a leading part, and was Chairman of the Council of that body.

## PHOTOMETRIC NOMENCLATURE

A PAPER by Mr. A. P. Trotter, read on May 21st before the Illuminating Engineering Society, discussed certain suggestions regarding photometric nomenclature contained in an American report by Prof. Blondel, Dr. Kennelly, Dr. Rosa, and Prof. Sharp. This Committee chose "luminous flux" as the fundamental quantity, and not, as might appear more natural, "candle power." The latter is defined as "luminous intensity expressed in candles," and luminous intensity is defined as the solid angular density of the luminous flux emitted by the source in the direction considered, or it is the flux per unit solid angle from that source. Mr. Trotter remarks that the term "candle-power" is used in two senses. In one sense it connotes an abstract idea like area or pressure, and in the other it is a vector quantity, and denotes a definite physical magnitude. In the former sense it is synonymous with "luminous intensity," but has taken such a hold on the English language that it is difficult to get rid of it. In the latter sense, the name of the physical unit of luminous intensity, the "candle," may often be substituted for "candle-power."

Mr. Trotter thinks that the expression intensity deserves some consideration before adoption, and rather objects to the definition of candle-power as a solid angular density. The American Committee defines illumination on a surface as the luminous flux-density over that surface, or flux per unit of intercepting area—and the definition of the unit, "Lux," a unit of illumination equal to one lumen per square meter," sends us wandering over the definition of flux-density and its unit—"Lumen—the unit of luminous flux, equal to the flux emitted in a unit solid angle (steradian) by point source of one candle-power." To this is added a footnote, "A uniform source of one candle emits  $4\pi$  lumens." Mr. Trotter criticises these definitions severely, considering them unintelligible, and objecting to the introduction of  $4\pi$ , and holding that the lumen should be a derived and not a fundamental unit. It is proposed to call a lumen per square meter a "phot," with a practical unit of a milli-phot (1 ft.-candle = 1.076 milli-photos). The name "exposive" is suggested as the product of illumination of time, and the "phot-second" as the unit. The term "brightness" has two senses—emissive brightness of a source of light, and reflective brightness of an illuminated surface. The American definitions refer only to the former, and measure it in candles for square centimetre. Various other definitions were quoted in the Paper without criticism, and in conclusion some of the symbols used in different countries for photometric quantities were reviewed.

In the course of the discussion, Mr. C. C. Patterson (National Physical Laboratory) defended the use of candle-power supply as a numerical value, and the treatment of luminous flux as the fundamental idea. He also suggested the term luminous capability in place of luminous intensity. Mr. H. T. Harrison and Mr. K. Edgecumbe, however, agreed with Mr. Trotter's view. A number of other members also spoke.

**Electric Cars at the Motor Van Parade.**—At the eighth annual Parade of Commercial Motor Vehicles held by the Commercial Motor Users' Association on Monday, a slightly larger proportion of electric cars took part than on previous occasions. Out of the total of 508 entries this year, 13 were electric vehicles, as against 5 out of 372 last year, and none in previous years. A special prize was this year offered to drivers of Edison battery vehicles. The whole of the electric cars entered were driven by these batteries, and of them three were entered by Edison Accumulators, Ltd., and the remainder by Harrods, Liberty's, and Lyons. One Tilling-Stevens petrol-electric mail van was entered by T. Tilling, Ltd.

**The San Francisco Engineering Congress, 1915.**—A special section of this Congress, which is to be held at San Francisco on Sept. 20th to 25th, 1915, is to be devoted to materials of engineering construction. The subject matter is divided up into specialised divisions, several of which will interest electrical engineers.

## ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

### THE PRODUCTION OF STEEL DIRECT FROM ORE IN THE ELECTRIC FURNACE

A PAPER by E. Humbert and A. Hethey, submitted to the recent meeting of the Iron and Steel Institute, described a series of experiments on the direct production of steel from Swedish and other ores in a 6-ton Héroult single-phase arc furnace. The energy consumed varied from 2,459 to 2,862 kw.-hours per ton, and very satisfactory qualities of tough steel were produced. The authors come to the conclusion that with the aid of the modern electric furnace the economic manufacture of steel direct from ore is a practical possibility. The material produced will, they say, be superior to that manufactured by present methods. A special type of furnace will probably be developed, although the standard Héroult furnace is satisfactory for occasional charges. The charge should lie deep in the furnace, to permit violent ebullition of the bath without overflowing. Anthracite electrodes will probably be found most satisfactory, owing to their freedom from breakages. The best use for this process will be found in countries that possess readily available sources of water-power and where deposits of pure rich ores can be obtained. Its most useful sphere will probably be found in making high-grade steels for springs, drills, and similar tools, shafts, and all grades requiring exceptional toughness. Such a process has the economic advantages of one operation instead of several, one furnace instead of a large and complicated plant; simplicity, cleanliness, and ease of control; ability to use refractory and richer ores; freedom of the steel from impurities; speed of manufacture. General cost depends largely on cost of electric power, but will be cheaper than the electrical production of steel from pig-iron; less labour, and efficient control of quality of steel obtained.

### A THREE-PHASE ARC FURNACE IN CANADA

A SOMEWHAT new design of three-phase arc furnace of 300-kw. capacity is being used by a new Toronto Company, known as Moffat-Irving Electric Smelters, Ltd., and is said to yield a high grade steel from ore fines, a waste product of blast furnaces. The crucible is built on a substantial base of concrete, says *The Electrical News* (Toronto), while above this hard burnt red bricks are used, and finally the main body is built up of silica brick. The ore, in a finely divided state, is fed into the upper portion of the furnace by a mechanical screw feed. Limestone is similarly fed in at the same level, and the necessary carbon is fed in at the bottom of the stack, which is enlarged at the bottom to form the reducing chamber proper. By this arrangement the ore and lime fall several feet through carbon monoxide gas at a temperature over 2,000° F., and as a result over 80 per cent. of the ore is reduced and the carbon dioxide escapes at the top. The furnace is run in the neighbourhood of 70 volts, so that the current is 2,500 amperes is required. The pressure can be varied about 20 per cent. up or down, according to the stage of the reduction. Regulation of the electrodes, which are of graphite 5½ in. in diameter, is effected by hand. Content analyses and physical tests have been made, and show the following composition of the steel: silicon, 0.27; manganese, 0.70; carbon, 0.29; phosphorus, 0.31; sulphur, 0.31. The physical tests yielded a 27.5 per cent. elongation on a 2 in. bar; elastic limit, 52,000 lb. per sq. in., and ultimate tensile strength, 78,000 lb. per sq. in.

**Ignition of Gas by Sparks.**—Mr. Sydney F. Walker writes in connection with the Senghenydd report that, as the result of experiments made in the earlier days, he takes the view that it is not a spark *per se*, nor a particular voltage that ignites gas, but the delivery of a certain quantity of energy either as a spark or in a heated wire or other way which causes ignition, and he mentions 10 watts as being sufficient to ignite a mixture of town gas and air. Mixtures of methane and air are less sensitive than lighting gas and air.

### A METHOD OF DRYING AIR FOR BLAST FURNACES

THE efficiency of blast furnaces is greatly increased by the removal of moisture from the blast, and plant for effecting this is one of the recent departures in blast-furnace practice. The effect of moisture in the blast is to cool down the contents of the furnace at the point of admission of the air, since heat is required from the charge to raise the temperature of the moisture. The important reactions therefore take place higher up in the furnace, and the nett result is a reduction in its capacity. Moreover, in the presence of excess of moisture the chemical reactions are not of the desired nature. Many ways in which the moisture can be removed are in existence, the majority involving the use of some chemical substance, such as chloride of calcium, to absorb the moisture. These processes, however, leave much to be desired in the efficacy with which they remove the moisture, and a method is coming into use in which the

MOTOR-DRIVEN REFRIGERATING PLANT FOR SEPARATING  
MOISTURE FROM FURNACE BLAST AIR.

atmospheric moisture is converted into snow which can be readily removed.

A large plant, working on this principle, has recently been installed in the Midlands. It consists of six 400-h.p. continuous-current "Witton" motors, driving "Haslam" ammonia compressors; the accompanying illustration gives an excellent view of this plant. The motors have interpoles and cast-steel shells, and are controlled by switchgear standing by each set. The ammonia compressors form part of a refrigerating plant, producing cold brine which cools a series of pipes. The blast is passed through these pipes, which are in duplicate, and the snow is removed from the interior surface of one set at frequent intervals, the other set meanwhile being in commission for the refrigerating process. After the moisture has been removed, the blast passes on to the blowing engine. The electric motor equipment for this installation was supplied by the General Electric Co., Ltd., of Witton, Birmingham, and 67 Queen Victoria Street, London, E.C.

**Presentation.**—On May 9th, at the annual meeting of the South Wales Branch of the Association of Mining Electrical Engineers, Mr. Sydney F. Walker was presented with a gold watch by members of the branch as a token of esteem and respect in connection with his four years' presidency of the Branch. The presentation was made by Mr. G. Williams, of Aber Peryn, the present President.

**Hydro-electric Power in Indian Gold Mines.**—It is reported that owing to shortage of water in the Cauvery River, the supply of water-power to the Kolar gold mines has been reduced and their operations curtailed. Work is in hand for further water storage.

## LIFTING MAGNETS IN STEEL WORKS

ALTHOUGH many of the functions performed by lifting magnets in steel works involve the retention of the magnet in a fixed position, it is also often found that a considerable amount of work can be done by a magnet in different parts of the works, in each of which it would not pay to install a separate magnet. It is sometimes advantageous in such a case to provide a complete equipment, consisting of a steam-driven generator, in conjunction with a crane which can be moved about as required. A complete

WITTON-KRAMER SELF-CONTAINED CRANE  
AND MAGNET EQUIPMENT.

equipment, including a De Laval steam turbine and a 42-in. Witton-Kramer magnet, is shown in the accompanying illustration. At the moment of taking the photograph the magnet was engaged in the stacking of steel ingots, though at other times it is utilised for removing scrap and hot ingots. This complete equipment was supplied to a large Sheffield steel works by the Witton-Kramer Electric Tool & Hoist Co., Witton, for whom the General Electric Co., of 67 Queen Victoria Street, E.C., are the sole selling agents.

**Castleford Collieries.**—The Allerton-Bywater Collieries and the Ledston Luck Colliery, of Castleford, were visited a short time ago by a party composed of members of the Midland Institute of Mining, Civil, and Mechanical Engineers, and the Midland Counties Institution of Engineers. The Allerton plant was modernised five years ago, and includes a turbo-generator for supplying power for the workings. Arrangements have been made whereby the supply of the Yorkshire Electric Power Co. can be utilised during repairs to the plant or similar contingency. Large economies have been effected owing to the installation of the new plant. Formerly, when the output was between 9,000 and 10,000 tons a week, seventeen Lancashire boilers were in use; at present, with a weekly output of 17,000 tons, only five boilers are needed.

**International Congress of Mining, Metallurgy, and Engineering.**—The sixth International Congress of Mining, Metallurgy, Engineering and Economic Geology is to be held in London from July 12th to 17th, 1915, and an executive committee, of which Dr. Arthur Cooper is chairman, has already been formed. It will be remembered that the last Congress of this nature was at Düsseldorf in 1910. Electrical matters will be dealt with both in the metallurgical and engineering sections. Further information can be obtained from the Secretary to the Congress at 28 Victoria Street, S.W., from whom a copy of the bye-laws, on a form of application for membership, can be obtained.

**Verband Deutscher Elektrotechniker.**—At the 22nd annual meeting of the German Institutions of Electrical Engineers at Magdeburg on May 26th a monumental tablet to the memory of Werner von Siemens was unveiled, and lectures were given on recent progress in electrochemistry and electrometallurgy, electric steel refining, wireless telegraphy, and electricity on board ships. Prof. Dr. Klingenberg, of Berlin, was elected President of the Verband for the year 1914-15. Herr Dettmar announced that the specification of the Verband for lightning protection of buildings had been accepted as standard by a large number of municipalities and other governing bodies.

## ELECTRICAL MINING AND METALLURGICAL PATENTS OF MAY

### Mining.

**D**URING the last month, the following specifications which deal with subjects of interest to mining electrical engineers have been published by the Patent Office:—No. 5,568 of 1913, G. J. Ralph, of Four Oaks, describes a combined portable electric lamp and fire-damp detector. The Wheatstone bridge principle is utilised. One arm of the bridge consists of a wire of platinum. Any inflammable gas coming in contact with the wire raises its temperature, and therefore its resistance, by catalytic action, and causes a galvanometer needle to deflect. A sliding contact is provided for bringing the needle to zero again. The percentage of fire damp present can be judged from the final position of this contact. An electrically operated rock drill, in which two solenoids are used to give a reciprocating motion to the drill, forms the subject of Specification No. 9,893 of 1913, by T. F. Wall (Birmingham). Siemens-Schuckertwerks Ges. of Berlin, in their Specification No. 11,313 of 1913, describe a method of control for A.C. commutating motors. Two levers only are used, one of which determines the position of the brushes and the other alters the stator connections for backward or forward running. Braking resistances are inserted in the circuit during lowering operations.

### Metallurgical.

Specification No. 6,911 of 1913, by O. Voigtländer (Essen, Germany), relates to the manufacture of tungsten. A mixture of tungsten trioxide and aluminium is burnt in a strongly heated furnace, in the presence of an inert gas. Pure homogeneous tungsten is said to result from this process. A method of copper refining by heating the metal in a furnace in the presence of the hot gases produced by the combustion of the fuel, is described by W. S. Rockey and H. Eldridge (New York) in Specification No. 7,409 of 1913. Oxidation of the fused metal is also prevented by pouring and ladling it in an atmosphere of these hot, reducing gases. An improved process of manufacturing aluminium nitride forms the subject of Specification No. 23,740 of 1913, by Soc. Gen. des Nitrures (Paris). A mixture of alumina and carbon is heated in an atmosphere containing nitrogen. The mixture is caused to pass along a tube which can be heated electrically to the required temperature. A further improvement in the above process whereby the furnace is divided into sections, with electrodes between every two sections so as to allow efficient heating of the interior, is described in Specification No. 24,347 of 1913, by the same patentees. Another invention also relating to electric furnaces is set forth in Specification No. 29,259 by J. I. Bronn and W. Schemmann (Rombach). It has been found that, in ordinary electric furnaces, the hot gases tend to escape through the furnace casing where the electrodes are led in, thus causing the latter to be gradually eaten away at this point. To prevent this, the electrodes are surrounded by a hollow cast-iron ring having perforations at the inside circumference, through which air, steam, or inert gas can be blown on to the electrode just above the point where it enters the aperture in the furnace, so as to drive back the hot gases and keep the electrode from being consumed. The Sodium Process Co. (U.S.A.), in a communication to G. B. Ellis, of London, describe an improved type of cathode for use in electrolytic furnaces. It is dealt with in Specification No. 29,418 of 1913, and consists of a large hollow tube of cast iron surrounding a smaller one, and electrically and mechanically connected to it at the top. The current thus has to flow in reverse directions through the cathode, so that the resulting magnetic effects neutralise each other.

**An Electrical Exhibition in Holland.**—In connection with a large electric power scheme in the province of Groningen, where a large power-house is being established, from which power will be distributed over a large area through about 50 sub-stations, an exhibition is being arranged at Helpman-Groningen in August and September next, where the applications of electricity to agriculture and small industries, as well as in the home, is to be demonstrated.

**Yorkshire Local Section of the Institution of Electrical Engineers.**—The result of the ballot for the election of members of the committee for next session has resulted in the election of Messrs. E. A. Barker, H. Bell, W. E. Burnand, and J. H. Schnauber. The committee will therefore be constituted as follows: Messrs. W. Emmott, Roslyn Holiday, Wilson Hartnoll, Thos. Roles, W. B. Woodhouse, H. E. Yerbury, W. M. Roger-son, W. Lang, H. A. Nevill, F. J. Lowe, E. A. Barker, H. Bell, W. E. Burnand, J. H. Schnauber.

## ELECTRIC TRACTION NOTES

The Italian Government has recently published details of the latest developments in the three-phase electrification of the State railways. The main lines near Genoa have been equipped for electric traction with overhead conductors. The locomotives have each a capacity of 2,000 h.p. and weigh 60 tons. The two motors are three-phase, 3,000-volt, 15-cycle machines, arranged to run in cascade and parallel, giving two synchronous speeds of 112½ and 225 r.p.m. They are mounted on a raised platform, and drive through crank pins and connecting rods. The starting resistances are of the water rheostat type, and the controllers are arranged to allow the locomotives to be run in multiple if required. The transmission is at 13,000 volts, transformation down to 3,000 volts being effected at four transformer stations, each of which is equipped with a three-phase transformer of the oil type, with a capacity of 3,600 k.v.a. These transformers are designed for 13,000 volts, but are adaptable to 22,000 volts by a change of connections. The power-house is situated at Chiapella, in Genoa, and contains two three-phase steam turbo-alternators, each giving 5,000 kw. at 13,000 volts and 15 periods.

The first of the new Westinghouse 8,000-kw. turbo-generators at the Greenwich Power Station of the London County Council Tramways was formally inaugurated last Thursday by Mr. G. H. Hume (Chairman of the Highways Committee).

The net profits from the Manchester Corporation Tramways last year amounted to £200,309, after meeting all capital charges. It is proposed to hand over £108,000 to relief of rates, and to carry the balance to reserve, renewals, and depreciation account.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Apropos of the recent statements in the Press regarding the installation of check call-meters at the subscriber's end of the telephones, we are informed that the scheme is as yet only in the experimental stage. Several different arrangements have been tried in the private exchange at the Post Office buildings, Roman Bath Street, E.C., with varying success, and we hope to be able to publish shortly some details of the one finally adopted. Some general details of the scheme are given in ELECTRICAL ENGINEERING, December 25th, 1913, page 729.

On Tuesday, May 26th, the new wireless stations for communication between Germany and America were tested for the first time under commercial conditions. The two stations (erected by the Hochfrequenz-Maschinen Akt.-Ges., the German company owning the Goldschmidt patents) are at Eilvese (Hanover) and Tuckerton respectively. According to the *Frankfurter Zeitung*, a dispatch of 3,000 words was sent from Tuckerton on Thursday and was received without any faults and without any repetition being necessary, in the course of a few hours. In January last, when only receiving apparatus was installed at Tuckerton, an official dispatch from the Kaiser to the President of the United States was successfully transmitted, but Thursday's message was the first under commercial conditions. The distance traversed is 4,000 miles. This Hochfrequenz system, it will be remembered, includes the Goldschmidt high-frequency generator.

The Merchant Shipping (Convention) Bill just introduced by the President of the Board of Trade makes certain amendments of the law relating to merchant shipping in order to give effect to the recommendations of the International Convention for the Safety of Life at Sea, signed in London in January this year. Part 3 relates to wireless telegraphy, under which it is provided that every ship registered in the United Kingdom carrying 50 or more persons shall be provided with a wireless installation, and also with certified operators and watchers. A new signal, called the safety signal, TTT, which is to be repeated at short intervals ten times at full power, is laid down for use by wireless stations which have to transmit to ships urgent information as to icebergs, derelicts, approaching storms, or other dangers. The master of every British ship is also compelled under penalty to report by wireless telegraphy or otherwise, as soon as possible, any dangerous ice, derelict, or other danger to navigation.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,394.

The diagram shows the connections of a single-phase induction motor which is used for driving some rubber-grinding machines. The main shafting is fitted with fast and loose pulleys, so that the motor can be started on no load. In spite

of this, the belt has to be pulled round before the motor will start. The supply is single-phase, 50 cycles, 220 volts, and the motor is rated at 5 h.p., 935 r.p.m. Is there any way of getting the motor to be self-starting?—"SIMPLEX."

(Replies must be received not later than first post, June 4th.)

### ANSWERS TO No. 1,392.

If there is a rise in frequency in a system owing to speeding up of the generator, the watt-hour meters are caused to run slow. What is the explanation of this, and what is the relation between the change of frequency and the slowing down of the meters?

The first award (10s.) is given to "J. E. R. R." for the following reply:—

Almost all meters register slow on a frequency higher than normal, but the errors are greater in some meters than others, and generally are greater in induction type meters than in the dynamometer type. For service work induction meters have placed the dynamometer type meters quite out of the field of alternating currents on account of the small size, cheapness, ease of adjustment, and calibration. With induction meters, the type most likely referred to, slow registration on increased frequency is due to a combination of alterations. In the first case the flux in both series and shunt magnets goes down as the frequency increases, as in any iron circuit magnetised by alternating current, and as the driving torque of the disc is approximately proportional to the product of these two fluxes the speed of the disc decreases as the square of the increase of frequency. The eddy currents in the disc which also help to create the driving torque will, however, increase with the increase of frequency, but owing to rotation the former action predominates, resulting in a decrease. Another result of increasing the frequency is an alteration in the phase angle between the driving fluxes, again tending to cause slow running. It also upsets all the adjusting devices for friction and quadrature.

The error differs greatly with different makes of instruments. On instruments of the high torque type, where a comparatively

large driving flux and strong brake magnets are used, the error in most cases is negligible, but in the case of the cheaper instruments, where the fluxes are light and the braking magnets weak, the error may become appreciable. An illustration is seen of this in the curves given below. Curve X is for

one of the former types, whilst curve Y is for a cheaper type. It will be seen how rapidly the error increases, directly the frequency gets above normal, in the cheap meter.

Some meters are added to inducing eddy currents in their cases, and in such instruments it is obvious that increasing the frequency will make them worse.

The second award (5s.) is made to "A. G. R.," who writes as follows:—

As we are dealing with an A.C. system, it is safe to assume that the watt-hour meters are of the induction type. The current through the pressure coil circuit of such a watt-hour meter is given by the equation—

$$I = \frac{E}{\sqrt{R^2 + X^2}}$$

where  $R$  = the resistance, and  $X$  = the reactance of this circuit. The variation in  $R$  will only be due to temperature changes, which need not be considered in this problem; but  $X$ , which is equal to  $2\pi\mu L$ , varies with the frequency.  $L$  = self-induction of the pressure coil circuit. Hence  $I$  will increase with decrease in the frequency, and vice versa. This change in current, due to variation in frequency, will cause a corresponding change in the voltage coil flux, and as the torque is proportional to the product of the maximum values of the voltage coil and current coil fluxes, it will vary also.

The expression for the torque may be written—

$$T = KF_v F_c \sin \theta$$

where  $F_v$  and  $F_c$  = maximum values of the voltage coil, and current coil fluxes respectively—

$\theta$  = the phase difference between them.

$K$  = a constant.

Again, owing to the inductance of the pressure coil, the angle of lag,  $\alpha$ , of the pressure coil current may be obtained from  $\tan \alpha = \frac{X}{R} = \frac{2\pi\mu L}{R}$  i.e., the tangent of this angle of lag

varies directly with the frequency. Also one may assume, without introducing any great error, that the voltage coil flux is in phase with the voltage coil current; so that it is evident that the angle  $\theta$  in the expression for torque is dependent on the frequency. Therefore a variation in frequency produces two effects: (1) increases or decreases the voltage coil flux, and (2) changes the phase relationship between the two operating fluxes. An increase in frequency will decrease the voltage coil current, but increase the phase difference. Now in the case under consideration the decrease in current will be greater than the increase in  $\sin \theta$ , and therefore the torque will decrease, and the meters will run slow.

The accompanying table shows the accuracy of a typical induction type watt-hour meter on different frequencies. The load and voltage were kept constant, and the meter was adjusted to be correct on 60 periods.

Frequency ..	40	50	60	70	80	90	100	110	120	130
Error % .....	-0.2	-0.1	—	-0.1	-0.3	-0.6	-1.0	-1.6	-2.5	-3.5

It will be seen that there is, in this case, a falling off in accuracy both with increasing and decreasing frequency. At small loads the error is generally increased, a 5 per cent. variation in frequency often causing a 1 per cent. to 2 per cent. error on half-load unless the instruments are carefully compensated. Electrodynamometer type watt-hour meters, when used on A.C. circuits, are not appreciably affected by changes in frequency unless the inductance of the coils is excessive; on the other hand, changes in power factor introduce considerable errors if the meter is not properly adjusted and elaborately compensated. The superiority of the induction over the dynamometer type on A.C. has practically confined the use of the latter to D.C. circuits.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published May 28th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

7,784/13. **Regulation of D.C. Generators.** A.E.G. In the ordinary shunt-wound machines, voltage regulation is only possible between narrow limits because of the instability of potential when the field is much below saturation. This invention avoids the above difficulty by eliminating one or more pairs of poles, when the voltage has to be reduced. The remaining poles still work at or near saturation, thus ensuring stability. The poles which are eliminated are first shunted by a resistance which is gradually cut out until the windings for these poles are short-circuited. This resistance can be afterwards used as an ordinary shunt regulator, in series with the remaining field windings. Five figures.

10,416/13. **Motor Control Panel.** A. H. RAILING and C. C. GARRARD. A fool-proof motor-starting device, in which the starting and shunt rheostats are operated by the same hand-wheel, which operates and is also electrically connected with, the circuit-breaker or switch. Thus the starting resistance cannot be cut out, until the switch has been closed. A similar arrangement may also be applied to A.C. motors. Two figures.

10,918/13. **Half-Watt Lamps.** B.T.H. Co. (*G.E. Co., U.S.A.*). The filament which is enclosed in a comparatively large spherical or pear-shaped bulb, consists of a squirted or drawn tungsten wire about 10 mils. diameter. It is supported on stout wires of wrought tungsten, sealed into the bulb. The inside of the bulb contains absolutely pure dry nitrogen at a pressure preferably equal to about atmospheric when the lamp is cold. Five figures.

29,418/13. **Electrolytic Furnace.** G. B. ELLIS (*Sodium Process Co.*). In the ordinary type of these furnaces, the cathode consists of a hollow tube of cast iron projecting up through the bottom of the furnace, and the deposited metal, such as sodium, being lighter than the electrolyte rises to the top of the furnace chamber, and forms a conducting layer which acts as an extension of the cathode. It has been found that when very heavy currents are used, objectionable magnetic reactions occur between the cast-iron cathode and the metallic layer. The above invention is intended to obviate this by surrounding the cathode by a hollow cast-iron cylinder of larger diameter, electrical connection between the two cylinders being made only at the top. The current thus has to flow through the cathode first in an upward direction through the outer cylinder, and then in a downward direction along the inner cylinder. Magnetic effects are thus avoided. Three figures.

11,106/13. **Wireless Signalling.** MARCONI WIRELESS TELEGRAPH Co. and C. P. RYAN. Signals are sent out at regular intervals, preferably by means of a pendulum. These signals are received in the ordinary way through a detector and relay, which causes an electromagnet to attract a pendulum or balance-wheel whose period of oscillation is equal to the interval between each signal. The amplitude of the swing of the pendulum is thus increased until the latter trips a contact, which gives the alarm. By allowing different intervals between the signals and having two or more contact trippers at the receiving station, different alarms can be given.

5,535/14. **Wireless Telegraphy.** G. LEIMBACH, Ph.D. The antennae are embedded in the earth, and consist of freezing tubes similar to those used in shaft sinking. By this means insulation from underground water is obtained. The effective length of the antennae is the amount which extends below the lower level of the underground water. By increasing this length, the range of communication can be extended if desired.

## Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** RAILING and ANGOLD [Arc lamp] 12,919/13; GEB. SIEMENS & Co. [Searchlight electrodes] 28,286/13; HUGHES [Arc lamps] 2,737/14.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** GRAHAM and RICKETS [Low-pressure distribution from high-pressure mains] 10,920/13; LEITNER [Circuit control] 11,115/13; RESISTO-ELECTRICAL MFG. Co. and RUZICKA [Insulating material] 11,975/13; GIRARDELLI [Control system for motors] 1,265/14.

**Dynamos, Motors, and Transformers:** ROSENBERG [Synchronous motors] 11,506/13; KLINKENBERG [Motor-braking devices] 13,135/13; HEINZ [Converter] 28,630/13; KEMP & LAURITZER [Transformation of A.C. currents] 8,021/14.

**Electrometallurgy and Electrochemistry:** HUNT and GIDDEN [Electrolytic sulphate process] 11,634/13; SOC. ANON. "LE FER" [Electrolytic iron] 16,565/13.

**Heating and Cooking:** VENNER [Heating elements] 13,988/13; BENSON & Co. and SIMS [Heating appliances] 26,462/13.

**Ignition:** ELECTRIC IGNITION Co. and COX [Spark plug] 15,974/13; SCHRÖTER & KÜSTER [Contact breakers] 28,535/13.

**Incandescent Lamps:** LAX [Pocket lamps] 18,733/13; BENJAMIN [Pavement lights] 23,770/13.

**Instruments and Meters:** KELVIN & JAMES WHITE, LTD., and FIELD [Mariners' compass] 11,561/13; EDELMANN [Alarm thermometers] 9,570/14.

**Telephony and Telegraphy:** SOLDATENCOW [Printing telegraph] 3,326/13; CORWIN [Telephone exchange system] 11,177/13; MARCONI [Wireless telegraph transmitters] 11,371/13; MARCONI'S WIRELESS TELEGRAPH Co. and FRANKLIN [Wireless receivers] 11,453/13; WANIBUCHI [Localising electromagnetic waves] 17,164/13; GRAHAM [Telephone receiver] 26,288/13; STEIDLE [Automatic telephony] 26,602/13; GRAHAM [Watertight telephone] 26,708/13; CHAUDET [Crystal detectors] 2,935/14.

**Traction:** MUNRO and R. E. T. CONSTRUCTION Co. [Trolleys for vehicles] 3,857/13, 11,629/13.

**Miscellaneous:** MYLO [Annunciator for bells] 11,191/13; GREVILLE [Medical appliance] 11,274/13; SMITH and TURNER [Exercising apparatus] 4,321/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos, Motors, and Transformers:** GASNIER [Machines for use on motor-cars] 11,244/14.

**Electrometallurgy and Chemistry:** LEVIN [Electrolytic apparatus] 3,654/14.

**Instruments and Meters:** VERTRIEBS GES. MAGNET ELEKTRISCHER APPARATE [Water-level indicator] 7,462/14; CHAPMAN [Electrically-heated instruments] 8,814/14.

**Storage Batteries:** BEAUPEL [Accumulators] 11,325/14.

**Telegraphy and Telephony:** DE LANGE [Thermo telephones] 4,184/14; PLEJEL [Loading coils] 8,185/14; SIEMENS & HALSKE AKT.-GES. [Telephone systems] 11,211/14.

**Switchgear, Fuses, and Fittings:** SIEMENS SCHUCKERTWERKE GES. [Circuit breakers] 10,082/14.

## Opposition to Grant of Patents

6,369/13. **Telephone Exchange System.** D. H. KENNEDY and J. W. TURNER. Opposition has been entered to the grant of this patent.

1,862/13. **Earthing Clip.** F. TOWNSON. An appeal has been lodged from the Comptroller's decision to allow the grant of this patent.

## Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

10,580/00. **Electric Furnaces.** O. IMRAY (*F. Morani*). This invention relates to the construction of high-power furnaces. The connections between the electrodes of the furnace and the supply mains are in the form of metallic plates, which are water jacketed where the heating effect is greatest, and are clamped securely in position. The molten metal is drawn off from the furnace through longitudinal slits, which are water jacketed all round their edges, and are situated at the desired height in the furnace casing. In the case of alternating current furnaces, where more than two electrodes are employed, the latter must be arranged so that induction effects are minimised. Twenty figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, &c.:** M. BOUCHET [Wire coupling] 16,581/04.

**Dynamos, Motors, and Transformers:** B. T.-H. Co. (*G. E. Co., U.S.A.*) [Dynamo windings for three-wire systems] 3,189/05.

**Storage Batteries:** ACCUMULATOREN FABRIK AKT.-GES [Accumulator plates] 27,221/09.

**Switchgear, Fuses, and Fittings:** J. H. TUCKER [Tumbler switch] 3,492/04.

**Telephony and Telegraphy:** C. ADAMS-RANDALL [Microphones] 3,717/09.

**Miscellaneous:** J. W. BROWN [Electro hydraulic lifts] 3,477/03; H. A. CAMPICHE [Electric clocks] 3,449/04; L. J. BLAKE [Submarine signalling] 3,360/07; I. J. OWEN [Advertising device] 3,175/09.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 313. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**FANS.**—An artistic leaflet received from The Edison & Swan United Electric Light Co. (Ponders End, Middlesex) deals with the "Ediswan" electric fans. A great variety of sizes and types are illustrated, including their convertible type, which can be used either as a wall or table fan, the larger ceiling fan, which is suitable for the ventilation of large rooms or halls, and the porthole fan, which is adapted for drawing air into a room through a suitable aperture in the wall or ceiling. The fans are made to work with either direct or alternating current, and several types are provided with means for regulating the speed to obtain the degree of coolness desired.

**MOTOR AND GENERATOR PULLEYS.**—The latest pamphlet to hand from the British Thomson-Houston Co. (83 Cannon Street, E.C.) illustrates two types of pulley, which they are manufacturing for use on motors and generators. For the smaller sizes, up to 9-in. diameter, solid cast-iron pulleys are recommended; beyond this size it is thought advisable to make the pulleys with cast-iron arms and boss, and mild steel rim.

**BALING PRESSES.**—We have received from David A. Bridge & Co. (Castleton, Manchester) a new catalogue dealing with Cummin's patent hydraulic baling presses.

**MINING PLANT.**—A booklet from J. H. Holmes & Co. (Portland Road, Newcastle-on-Tyne) contains some very fine illustrations of some of their manufactures which are of special interest to mining engineers. They include D.C. generators, alternators, pumping sets, both centrifugal and reciprocating, and various types of haulage gear. In the larger sizes of the latter, double helical gearing is employed in obtaining the power from the motor shaft. A coal cutter and a motor-driven air-compressor is also illustrated. A large variety of switches, switch pillars, and controllers are included.

**CORRESPONDENCE INSTRUCTION.**—We have received from the Cambrian Correspondence Mining and Engineering School (Cemetery Road, Porth, Glamorganshire) a copy of their handbook giving a few particulars of the methods employed and sample papers set at the examinations for which their students are trained.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**ELECTRICAL PLANT.**—A comprehensive catalogue issued by the A.E.G. Electric Co., Ltd., should be of interest to everyone who is in any way connected with the consumption of electricity. It is divided into ten sections, and deals with almost every type of plant, apparatus, or fittings which are likely to be used in either household or workshop. The fact that lighting, heating, and cooking apparatus, fans, air compressors, and clocks all find a place in this booklet, may give some idea of its range.

**CELL TESTING VOLTMETER.**—A leaflet just issued by Crompton & Co., Ltd. (Chelmsford), describes a dead-beat voltmeter specially adapted for cell testing. A special feature of this instrument is the ease with which it can be manipulated.

**D.C. MACHINERY.**—A new 28-page catalogue published by the Adnil Electric Co., Ltd. (Adnil Building, Artillery Lane, E.C.), is devoted to their G.F. type D.C. dynamos and motors. The standard machines are shunt wound, with interpoles, but the windings can be made either series or compound at a slightly increased cost. The outputs of the motors range from 4 to 125 h.p., whilst the dynamo outputs vary from 3.5 to 90 kw. Although these machines are open type, a fan is employed to assist the ventilation, so that the outputs are exceptionally high. A list of D.C. motor-starters is also included. The tables showing the gross and net weights of the various sizes of machines and accessories will probably be of assistance to a large number of purchasers.

**ELECTRIC WINCHES.**—A considerable variety of designs of electrically-driven winches, both for shipboard use and for file driving, shipyard and dry-dock purposes, are described in an illustrated catalogue from the Sunderland Forge & Engineering Co., Ltd., 31 Budge Row, Cannon Street, E.C.

**TECHNICAL ADVERTISING.**—A little pamphlet entitled "Out of the Rut," calling attention to examples of attractive methods of advertising, is to hand from Ernest Ingram Hill (26 Stanton Road, Wimbledon, S.W.).

### ELECTRIC SALVAGE PUMP

IN marine salvage operations electrically-driven pumps of a size and type that will enable them to be lowered into flooded compartments through small hatchways, and to work entirely submerged, are often required. Modern vessels are of so great a depth that it is frequently impossible to pump out a flooded compartment by apparatus on deck, or through piping taken from pumps of a salvage craft alongside. The apparatus illustrated shows a submersible electric pump introduced by Messrs. Merryweather & Sons (Greenwich). The motor is of a standard type that can be run from current supplied by an ordinary ship-lighting equipment, and is

ELECTRICALLY-DRIVEN SALVAGE PUMP.

enclosed in a light galvanised steel watertight casing, with large doors at the end that can be readily opened when desired. The motor is connected direct to the spindle of a centrifugal pump fixed to the lower end of the motor-casing through a watertight stuffing box. Merryweather's special design of watertight terminals are fitted to the motor for the connection of the flexible cable. The complete apparatus can be slung from a tackle, and will work perfectly in such a position, or can be operated just as well when lying in a horizontal position. It can be lowered directly into the water, if facility of access permits, or to within a distance allowable for a length of flexible suction pipe to be got into

## DIE CASTINGS

must not only "look" all right: they must BE all right: they must leave nothing to chance: there must be nothing experimental about their adoption.

### "PRANA" DIE CASTINGS

(manufactured by the Firm who use them in their own business) are guaranteed to fulfil all these conditions.

*Accurate and Interchangeable.  
British-made—"Tough & True."*

**AERATORS, Ltd.** (Dept. EES) Upper Edmonton, London, N.

position. Owing to the general method of construction, the whole apparatus will safely withstand any amount of rough usage, such as it may get in a sea-way. It can also be rolled along a deck on its end flanges quite conveniently. These pumps are made in two standard sizes, with either one or two suction and delivery branches, each 6 in. diam., and capable of delivering 214 tons and 295 tons per hour respectively. Merryweathers particularly recommend this type of pumping apparatus to salvage masters, on account of the way in which power can be supplied from one vessel to another in a heavy sea way. For instance, a vessel can be taken in tow and the electric power cable laid along the towing hawser, thus allowing pumping operations to be kept up while making port.

### LAVIGNE ELECTRIC LOCKS

A SERIES of locks are now being manufactured by the Sun Electrical Co. (118-120 Charing Cross Rd., W.C.), which are fitted with an electric alarm device, for ringing a bell as soon as a key is inserted into the lock. The electrical construction, which is entirely enclosed in the lock

SHOP-DOOR HANDLE.

case, consists essentially of a contact piece held in position by light springs. When a key or similar article enters the lock, the circuit is completed, and the alarm comes into operation. The two connecting wires from the lock are intended to be concealed in the mouldings of the door and connected to the hinges, thus making it impossible for a

NIGHT LATCH.

would-be burglar to tamper with them. The same invention has also been applied to the ringing of shop-door bells, so that when the handle is turned to open the door, the bell circuit is completed. The illustrations show two typical applications of this device. The appearance of these locks

combines neatness with great mechanical strength. Although the standard type of lock is intended to be connected directly in the bell circuit, there is nothing to prevent the use of a relay, so that once the alarm bell had been started, it would continue to ring even after the key had been withdrawn from the lock.

### ELECTRIC TOLLING BELL

AN entirely novel construction has been adopted for the "Kingsway" Electric Tolling Bell, which has been put on the market by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.).

The bells are intended for any purpose for which a loud-sounding alarm is required.

The construction of the "Kingsway" Electric Tolling Bell is as follows:—The striking hammer is connected to a rod which is screwed into an armature, whose movements are controlled by a powerful electro-magnet through a peculiar form of contact. The electro-magnetic mechanism is con-

FIG. 1.

tained in the massive cast-iron box, and the moment current is switched on, the electro-magnets are energised, and attract the armature. This action causes the hammer to strike the gong, and at the same time the electric circuit is opened by the contact-breaker, and the hammer swings back to an equal amplitude the other side of the neutral position. When the hammer has commenced its return swing the electric circuit is completed, and the armature therefore again attracted, with the result that an extremely powerful blow is imparted to the gong. This cycle of operations is continued so long as the circuit is closed.

The vital part of the apparatus is the contact, and this is unique in its action and is self-cleaning, so that there is no likelihood of trouble arising from faulty contacts, and all sparking trouble is eliminated by the use of a non-inductive resistance connected directly across the contacts. By refer-

FIG. 2.

ence to Fig. 2, the construction of the contact-maker can be seen. The gongs are of best bell metal, and this, together with the slow-striking action of the movement (twice per second or less if the hammer rod is lengthened), allows of the full tone of the gong being obtained. The "Kingsway" Electric Tolling Bell is made in two sizes. In the first, the gong is approximately 12 in. in diameter, and averages 42 lb. in weight. The energy required is one ampere at 15 volts. In the second, which is for use where the sound is to be carried a very long way, the gong averages 182 lb. in weight, and is approximately 17 in. in diameter. The energy required is one ampere at 25 volts. In both cases, the mechanism is absolutely waterproof, and it can be fitted to existing hand-pulled bells. One remarkable point is the very low energy consumption whereby ordinary battery power is all that is required.

The makers will be pleased to send full particulars to those interested.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Atherton.**—Sanction is to be sought for loans of £850 for mains, £900 for transformers, and £250 for switchgear.

**Australia.**—A booster set for charging a battery of 288 cells is required by the N.S.W. Government Railways & Tramways Department. Copies of the specification may be seen at 73 Basinghall Street, E.C.

**Bicester.**—A proposal for the formation of an electric lighting company for this district is under consideration.

**Colne.**—Mr. S. J. Watson, Borough Electrical Engineer at Bury, has been asked to report with regard to new generating plant.

**Eastbourne.**—The Borough Electrical Engineer recommends the replacement of the existing switchboard with a more up-to-date pattern at an estimated cost of about £1,400.

**Harrogate.**—One 288 pipe economiser in three banks. June 22nd. (See advertisement on another page.)

**Plymouth.**—Mains extensions at an estimated cost of £260 are to be carried out.

**Russia.**—A loan of £124,000 is to be raised by the Nijni-Novgorod Municipal Authority for electric lighting.

**South Africa.**—The Worcester (Cape Province) Municipality invites tenders for a complete generating station; also transmission lines, street lighting, meters, and house wiring. Particulars from Professor Bohle, 25 Rosemead Avenue, Cape Town.

The Robertson Municipality is proposing to raise a loan of £10,000 for an electric lighting scheme.

**Stalybridge.**—The Joint Board proposes to erect a new power station.

**Stockton-on-Tees.**—A supply of three-core cable is required. Borough Electrical Engineer, June 12th. (See advertisement on another page.)

**Sunderland.**—A 1,200-kw. sub-station is to be erected by the Corporation Electricity Department for the River Wear Commissioners.

**Wrexham.**—A 300-kw. generating set with condenser is to be installed.

### Wiring

**Aberdeen.**—Electric lighting at police offices. City Architect, June 10th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Barrow-in-Furness.**—Three new schools.

**Bolton.**—Extensions at Messrs. Crosses & Winkworth's mill, Grant Street; also at Swan Lane Spinning Mill.

**Bristol.**—Extension of Art Gallery.

**Croydon.**—Fifty-four houses in Norbury Court Road. C. G. Allen, Norbury.—Six houses in Buller Road. Scratchley Bros., 111 High Street, Thornton Heath.

**Maidstone.**—New county police barracks (£80,000).

**Shipley.**—New spinning mill. Architects, Moore & Crabtree, 4 Exchange Buildings, Bradford.

### Miscellaneous

**Australia.**—Ninety-five common battery telephone switchboards are required by the Deputy Postmaster-General, Melbourne. Copies of the specification may be seen at 73 Basinghall Street, E.C.

**Colchester.**—Twelve months' supply of electrical sundries for Severalls Asylum, Colchester. Clerk, Severalls, Colchester.

**Darwen.**—Two double-deck tramcars are required. Tramways Manager, June 15th.

**London: L.C.C.**—Tenders are invited for, alternatively, 50, 100, or 150 complete trailer cars, and the equipment of 200 existing electric tramcars with couplers and traction gear for drawing trailers. (See advertisement on another page.)

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Falkirk.**—The contract for a twelve months' supply of meters has been placed with Messrs. Chamberlain & Hookham.

**L. & N.W. Railway.**—An order has been placed with the British Westinghouse Co. for high and low tension switchgear to the value of between £50,000 and £60,000 for the eleven sub-stations of the London & North-Western Railway. (See article on page 303.)

**Malvern.**—A contract for a 150-kw. generating set has been placed with Messrs. Bellis & Morcom and the British Westinghouse Co.

The tender of the General Electric Co., Ltd., for the supply of all types of Osram lamps has been accepted by the Comptroller of Stores, G.P.O., Bedford Street, London, W.C.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son, of 5, Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £65 to £65 10s. (last week, £65 5s. to £65 15s.).

**Liquidations.**—A meeting of the De Forest Wireless Telegraph Syndicate will be held at the offices of Messrs. Allen, Attfield & Co., 147 Leadenhall Street, E.C., on June 29th, at 12.30 p.m., to hear the liquidator's account of the winding-up.

**Bankruptcies.**—The last day for receiving proofs in the bankruptcy of J. Swainson, Electrical Engineer, 22 Bootle Street, Manchester, is June 16th. The trustee is A. Yearsley, 27 Brazennose Street, Manchester.

A first and final dividend of 8s. 3d. in the £ is payable in the bankruptcy of Charles Blake, trading as the Bilston Electrical Co., 4 Church Street, Bilston. The dividend is payable at the Official Receiver's Office, 30 Lichfield Street, Wolverhampton.

## APPOINTMENTS AND PERSONAL NOTES

Mr. E. G. Mawbey, Borough Surveyor at Leicester, has been awarded an honorarium of £500 in consideration of his having acted as electrical and civil consulting engineer to the Corporation tramways system since its inception.

Mr. C. Bottomley Smith, Chief Engineer to the old Hove Electric Lighting Co., and who, as we announced last week, has been transferred to a similar position under the Corporation, has been presented with a gold chronograph and sovereign-case, subscribed for by the staff.

A technical assistant and testing engineer is required in the Stoke-on-Trent Electricity Department. Salary, £140 per annum. (See advertisement on another page.)

An assistant lecturer is required in the Engineering Department of the Workington Technical School. Salary £120 per annum, with £10 increments. (See advertisement on another page.)

A traffic superintendent is required by an important telephone company abroad. (See advertisement on another page.)

**Electric Clocks.**—Three years ago, when Vickers, Sons & Maxim, Ltd., built their new offices, "Vickers House," Broadway, Westminster, various systems of electric clocks were brought to their notice, and they selected three for trial, allocating two floors to each. The Synchronome Co., Ltd. (32 and 34 Clerkenwell Road, E.C.), inform us that the test has now ended in favour of the Synchronome system, which is also installed at Messrs. Vickers' Sheffield, Barrow, and Montreal works. At a week's notice the Synchronome Co., Ltd., were required to add 52 clocks of a special type to the 73 Synchronome dials already installed. This was successfully achieved during the Whitsuntide holidays, and all was in order for the return of the staff on Tuesday morning. An electric time circuit of 125 dials in the administrative offices of a single firm probably constitutes a record.

## LOCAL NOTES

**Belfast:** *Position of Electrical Undertaking.*—The Tramways and Electricity Committee has decided to call in Mr. J. F. C. Snell to advise as to the present condition of the generating plant and with regard to further developments of the electricity undertaking.

**Bexhill:** *Officials as Consulting Engineers.*—A recommendation by the Electricity Committee that Mr. A. C. Ticehurst, the Assistant Electrical Engineer, should be allowed to advise the Battle Board of Guardians as consulting engineer has been rejected by the Council.

**Blackburn:** *Continued Progress of Electricity Undertaking.*—The accounts for the past year show that the undertaking has fully maintained the considerable progress shown during recent years. The installation of the new system of street lighting in the centre part of the town has been completed, and a noticeable feature of the applications for supply has been the large number received for the lighting of small residential property and shops in districts where mains are already laid, thus involving only a very small capital expenditure. A number of applications for supply by neighbouring local authorities are under consideration. The net profit for the year was £4,687, compared with £3,521 in 1912-18, after setting aside £350 for depreciation and, of course, meeting capital charges.

**Blackpool:** *Electric Cooking.*—A complete electric cooking equipment has been placed in the new Tower dining-room, which was opened on Saturday.

**Cleethorpes:** *Heating and Cooking.*—In consequence of the great demand for power for heating and cooking, the Electricity Committee is endeavouring to obtain a reduction in the price of current purchased from the Tramways Co. and used for this purpose.

**Grimsby:** *Large Electricity Profits.*—The net profit of £4,061 on the electricity undertaking for last year was much larger than had been anticipated in view of the high price of coal and large payments out of revenue for mains and meters. It has been decided to transfer £500 to relief of rates.

**Hightown:** *An Electricity and Gas Scheme.*—The only means of a public supply of lighting in this small town, which adjoins Liverpool, is petrol-air gas, but the Company supplying it is in liquidation, and has been purchased by a new company known as the Hightown Gas & Electricity Co. This latter was before Parliament last week asking for statutory powers in the district, and there was no opposition from the local council. There is, however, in the district a small generating plant owned by a lady, which supplies a few houses, and an overhead cable is carried across one of the roads with the permission of the Council. The owner of this generating plant petitioned against the bill, and urged that her undertaking should be purchased by the new company. A Committee of the House of Lords, however, decided that she had no *locus standi*, and the bill was sent forward for third reading.

**London:** *Islington: Guardians and Electric Lighting.*—With reference to the note on this subject on page 300 of our last issue, our attention is called to the fact that it would appear from this that Messrs. Hancock & Dykes are the consulting engineers to the Guardians for the proposed electrical scheme. This, however, is not the case. Mr. A. H. Dykes was merely retained just before the inquiry to give expert evidence in support of the application. The engineer to the scheme is Mr. J. S. Enright.

**Stepney:** *Electricity Accounts.*—The accounts of the Electricity Department for the year to March 31st show a net profit of £14,177, to which is added £1,481, brought forward from the previous year. The sum of £5,000 is carried to reserve, £4,182 for replacement of plant, &c., £2,723 is written off capital account in respect of assets now non-existent, and £2,305 towards expenditure in the nature of capital. The balance is carried forward.

**Manchester:** *Large Electricity Profits.*—The electricity undertaking last year showed a net profit of £36,000, of which £28,700 has been devoted to relief of rates. Of the balance £779 has been carried to general reserve, and the remainder is to be used for capital purposes. The number of units sold were 118,000,000.

**Nottingham:** *Large Electricity Profits.*—The net profit from the electricity undertaking for 1913-14 allows of the sum of £8,000 being transferred to relief of rates. In addition, £4,471 is carried forward.

**Nuneaton:** *Bonus to Electrical Workmen.*—As an appreciation of the good work carried out by the electricity staff last year, as a result of which a large profit was made and £500 transferred to the relief of rates, the Council has decided to present each workman with a bonus of one week's wages.

**Portsmouth:** *Electricity Profits for Relief of Rates.*—The Electricity Committee recommends the allocation of £3,000 from the profits of the electricity undertaking last year to relief of rates. In addition, the sum of £1,000 is to be placed to reserve and £364 to the fire insurance fund.

**Richmond:** *Street Lighting.*—The Richmond (Surrey) Electric Light & Power Co. is to give a demonstration in street electric lighting. At present the streets are lighted by the Brentford & Richmond Gas Cos.

**Sunderland:** *Another Record Year.*—The Electricity Department improved last year upon its record year of 1912-13, the output being 1½ million units more. The works costs are now down to 0·97d. per unit, which is again a record for the department. Mr. A. S. Blackman, General Manager of the Department, in his report, states that up to the present the cooking load has been deliberately held back on account of the difficulty of obtaining suitable apparatus, but trustworthy cookers are now available, and will, he anticipates, come largely into use in the near future. The net profit on the department last year was £10,087, of which £9,000 was carried to depreciation and renewal fund.

**Torpoint:** *Electric Lighting Abandoned.*—After considerable argument and discussion, the Council has decided not to go forward with the proposed electric lighting scheme.

**Walsall:** *Profits on Electricity Undertaking.*—The accounts of the electricity undertaking for the fifteen months to March 31st show a net profit of £925. The scheme for the erection of a new power station at an estimated cost of £74,850, referred to on page 275 of our last issue, has been sanctioned by the Council. The Committee pointed out, however, that had the contributions been payable quarterly, instead of yearly, there would have been a loss of £472.

**Wellington (Salop):** *Sale of Lighting Order.*—The Council has received an offer for the purchase of its Electric Lighting Order for a sum of £200. The Electric Lighting Committee recommends its acceptance.

**West Hartlepool:** *Waste Gas Scheme.*—There is a deficiency of £1,878 upon the working of the electricity undertaking last year, owing to the expenditure upon the new waste gas plant at the Seaton Carew Ironworks. The full benefits from this scheme will now begin to make themselves felt.

**Worcester:** *Capital Payments from Revenue.*—The accounts of the electricity undertaking for the past year, which show a deficiency of £505, do not really indicate the true strength of the position of the undertaking. For many years the Committee has carried out the policy of meeting many payments of a capital nature from revenue, which has made it impossible to show net profits. More satisfactory results are now looked for in the future, and the deficiency above mentioned is to be carried forward, as it is anticipated that the profits for the current year will more than cancel that amount.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Electric Construction Co.**—Considerable satisfaction was expressed with the results of the past year's working (ELECTRICAL ENGINEERING, May 14th, p. 276) at the annual meeting last week. Important extensions are being carried out to the works to enable the company to cope with its increasing trade.

**Madras Electric Supply Corporation.**—There was a loss of £10,525 for 1913, but this was not altogether unforeseen, as in their report for 1912 the directors warned the shareholders that the working for 1913 could not be otherwise than unsatisfactory consequent upon having to rely on the old plant to meet increasing load. Unfortunately, the position was aggravated by a breakdown of the boiler plant in the early part of the year. The scheme for the consolidation of the Supply Company and the Tramway Company has been brought into operation, and better results are looked for when the new generating plant is installed.

## SUMMARY

A 15,000 kw. turbo-alternator, running at 1000 r.p.m., has recently been put to work in the Manchester Electricity Works. (Page 316.)

THE Institution of Electrical Engineers are landlords of offices of the Women's Social and Political Union which were raided by the police on Tuesday. (Page 317.)

A LIST of members and others who have signified their intention of attending the Convention of the Incorporated Municipal Electrical Association at Birmingham is given. (Page 317.)

WE also publish portraits of the President of the Association and the readers of papers, together with descriptive notes on the works to be visited during the Convention. (Page 319.)

THE Summer Lane station of the Birmingham Corporation will be one of the principal visits, and the latest turbo-generators at this large works will be compared with the older reciprocating plant. (Page 320.)

TURBO-GENERATORS which have superseded reciprocating plant will also be seen at the Coventry Electricity Works. (Page 322.)

OF the manufacturing works visited, one of the most interesting from the electrical point of view will be the huge establishment of the General Electric Co. at Witton, where the engineering works, the fan and small motor works, the switchgear and arc lamp departments, the central stores, and the conduit works, will be inspected. (Page 322.)

AMONG other works to be visited which we describe are those of Belliss and Morecom, Birmingham,

Willans and Robinson, Rugby; The Daimler Motor Co., Coventry; and J. H. Tucker and Co., Birmingham; and the waterpower generating station at Worcester. (Pages 324 to 327.)

DURING the Convention, a demonstration of electric vehicles will be held. Illustrated descriptive notes are given of the vehicles which will probably be present. (Page 327.)

AN apparatus for the electrical transmission of images of moving objects is described. (Page 328.)

A PROCESS for bleaching wax by electrically produced ozone has recently been introduced. (Page 328.)

THE relative merits of different methods of wiring ceiling roses are discussed in our Questions and Answers columns. (Page 329.)

THE Committee of Engineers of the London electric supply co.'s are getting out a joint scheme for the re-organisation of electricity supply in London. (Page 329.)

A PATENT by the B. T.-H. Co. for the manufacture of low hysteresis steel, and one by G. Marconi relating to wireless transmission, were amongst the specifications published last week.—A Patent for an adjustable resistance box expires this week after a life of fourteen years, and four Patents relating to metallic filament lamps have been allowed to become void. (Page 330.)

THE working expenses of the Dolter surface-contact system at Lincoln is 5·91d., against 6·651d. for the Lorain system at Wolverhampton.—Mr. J. McElroy, General Manager of the Manchester Corporation Tramways, is convinced that the time is far distant when motor-omnibuses will supplant tramways.—The York Tramway Manager has reported against the "pay-as-you-enter" system. (Page 331.)

THE Committee on Wireless Telegraphy Research recommends the establishment of a permanent National Telegraphic Research Committee, with a special experimental equipment at the National Physical Laboratory. (Page 331.)

OUR Trade Section contains illustrated notes on a new watertight pull switch, on indirect lighting, and on decorative illuminations. (Page 332.)

LARGE expenditures upon new plant are contemplated at Sunderland, West Ham, Worcester, and Bexley; a lighting battery, booster, and switchboard are required at Stretford; transformers, motors, meters, and starting switches at Manchester; converting plant and switchgear at Bolton; cable at Antwerp; high-tension insulators at Sydney; rotary converters and frequency changers for the Melbourne suburban railways. (Page 333.)

THE Dundee electricity undertaking pays £6,500 in rates on an annual income of £61,000, against £5,800 by the Gas Department on an annual income of £158,000.—The charge for public arc lighting in Edinburgh is to be reduced by 30s. per lamp per annum.—A deputation from the Manchester Electricity Depart-

ment is to visit a number of large power schemes abroad.—In spite of losses, the Cleckheaton Council has refused to dispose of its electrical undertaking. (Page 334.)

THE whole of the lighting business of the Birmingham District Power and Traction Co. is now being transferred to the Shropshire, Worcestershire, and Staffordshire Electric Power Co. (Page 334.)

## ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 11TH.

*Royal Institution.*

3 p.m. Afternoon Lecture II. "Faraday and the Foundations of Electrical Engineering," by Prof. S. P. Thompson, F.R.S.

*Faraday Society.*

8 p.m. At Institution of Electrical Engineers. Presidential address on "Advances in the Metallurgy of Iron and Steel," by Sir Robert Hadfield, F.R.S.

FRIDAY, JUNE 12TH.

*Physical Society.*

8 p.m. At Imperial College of Science, South Kensington, S.W. (1) "A Magnetograph for Measuring Variations in the Horizontal Intensity of the Earth's Magnetic Field," by F. E. Smith. (2) "The Atomic Weight of Copper by Electrolysis," by A. G. Shrimpton. (3) "Note on an Improvement in the Einthoven String Galvanometer," by W. H. Apthorpe.

MONDAY, JUNE 15TH

*Incorporated Municipal Electrical Association.*

8 p.m. Birmingham Convention. Reception and Smoking Concert at Grand Hotel.

TUESDAY, JUNE 16TH.

*Incorporated Municipal Electrical Association.*

10 a.m. Birmingham Convention. Meeting at Midland Institute. (1) Presidential Address by R. A. Chattock. (2) "Commercial Development of Electrical Supply in Towns of Moderate Size," by W. A. Vignoles.

2.30 p.m. Demonstration of Electric Vehicles and Visits to Works of General Electric Co. and Belliss & Morcom.

7 p.m. Annual dinner at Grand Hotel.

WEDNESDAY, JUNE 17TH.

*Incorporated Municipal Electrical Association.*

10 a.m. Birmingham Convention. Meeting at St. Mary's Hall, Coventry. "The Design and Operation of Modern Boiler-House Plant," by S. E. Fedden.

2.30 p.m. Visits to Coventry Electricity Works and Daimler Co.'s Works.

8.30 p.m. Reception and Dance at Council House, Birmingham.

THURSDAY, JUNE 18TH.

*Incorporated Municipal Electrical Association.*

10.30 a.m. Birmingham Convention. Meeting at Memorial Lecture Room. "The Standardisation of Tariffs," by J. H. Bowden.

2.30 p.m. Trip to Warwick Castle.

8.30 p.m. Fête and Concert at Botanical Gardens.

"Point Fives."

10 p.m. Meeting and Supper at Grand Hotel.

FRIDAY, JUNE 19TH.

*Incorporated Municipal Electrical Association.*

10 a.m. Birmingham Convention. Annual General Meeting at Midland Institute.

2.30 p.m. Visit to Summer Lane Power Station.

8 p.m. Cinderella Dance at Grand Hotel.

SATURDAY, JUNE 20TH.

*Incorporated Municipal Electrical Association.*

10 a.m. Birmingham Convention. Visit to Worcester.

## A 15,000 KW. TURBO-ALTERNATOR AT MANCHESTER

THE most recent extension to the generating plant at the Stuart Street Station of the Manchester Corporation is the 15,000-kw. Howden-Siemens turbo-

further extension is in hand which is really a replacement, inasmuch as one of the original 1,500-kw. cross-compound vertical slow-speed Yates and Thom engines

15,000 KW. HOWDEN-SIEMENS TURBO-ALTERNATOR AT STUART STREET, MANCHESTER.

alternator which we illustrate here. With this addition, the capacity of the station is brought up to 55,000 kw. The engine-room is now practically full, although a

driving an A.E.G. alternator is being taken out for its space to be occupied by a 6,000-kw. turbo-alternator. When this has been accomplished, which will be about

the middle of 1915, no further extensions to the capacity of the Stuart Street Station will be possible. It is of interest to note that the units generated at Stuart Street last year were 123,388,190, and the maximum demand was 36,120 kw.

The main contractors for the set were James Howden & Co., Ltd. (Glasgow). The turbine is of the Zoelly impulse type, with 14 wheels, the largest overall diameter is nearly 9 ft. and the smallest nearly 8 ft. The shaft is 15½ in. at the journals and runs at 1,000 r.p.m. Main and emergency governors are fitted. All the bearings are water-jacketed, and are fitted with forced lubrication, in connection with which an oil cooler in the bed-plate is provided having no less than 820 square feet of cooling surface. The machine is designed to take steam at 190 lbs. per sq. in. at 600° F., and to exhaust into a 27½-in. vacuum.

The alternator to which it is directly coupled by a rigid coupling was made by Siemens Brothers Dynamo Works, Ltd., and its rated output is 15,000 kw. at 6,000 volts 50 cycles three-phase, with a temperature rise after six hours at full load not exceeding 60° F. on any part of the machine. The overload capacity is 19,000 kw. The stator is totally enclosed, and is wound with one mica insulated bar per slot. The rotor is of the cylindrical type, about 67 ins. diameter, made up of a central solid forging with steel rings shrunk over it. The windings are contained in equidistant slots. The total weight of the rotor is about 53 tons, and carries fans for axial ventilation. An external fan capable of delivering 53,000 cubic feet of air per minute, and driven by a 120 h.p. motor at 670 r.p.m., is also installed. Excitation is provided by a 220-volt shunt-wound exciter coupled to the end of the alternator shaft. As an alternative, excitation may be supplied from the station bus-bars. A wet-air filter has been supplied by the Sturtevant Engineering Co., but this works in parallel with dry-cloth air filters which had been previously installed.

The condensing plant was supplied by Richardsons, Westgarth & Co., Ltd. (West Hartlepool). The surface condenser, which is 11 ft. diameter by 16 ft. between tube plates, and is built up to ¾ in. mild steel plates, contains 6,550 tubes ¾ in. external diameter, giving a total surface of 24,000 sq. ft. Following the latest practice at Manchester, no main exhaust valve has been installed between the turbine and the condenser, but, in lieu thereof, arrangements have been made for flooding the steam space of the condenser whenever the set is exhausting to atmosphere. The air and water extracting pumps are of the kinetic type made by the Pulsometer Engineering Co., and consist of two units each equal to 60 per cent. of the capacity of the plant,

and driven by a 100-h.p. Richardson-Westgarth impulse steam turbine at 3,000 r.p.m. The whole of the exhaust steam from these turbines is utilised in the kinetic air ejectors and direct contact feed water heaters. The circulating water pumps are also divided into two units of similar proportions, and comprise a pair of multi-cellular centrifugal Rateau pumps each driven by a 600 h.p. Richardson-Westgarth impulse steam turbine. The guaranteed steam consumption per kilowatt-hour, with a power factor of 0.95, with a steam pressure at the stop valve of 190 lbs. per square inch at total temperature of 330° F. and a 27½-in. vacuum, are as follows:—¼ load, 16.95; ½ load, 14.92; ¾ load, 14.12; full load, 16.35; and 25 per cent. overload, 14.25. In considering these figures, it must be remembered that Stuart Street is a cooling-tower station, and therefore very high vacua are not obtainable.

The whole plant is to the specifications of Mr. S. L. Pearce, Chief Engineer to the Manchester Corporation Electricity Department, to whom our thanks are due for the information from which this description is prepared.

## THE INSTITUTION OF ELECTRICAL ENGINEERS AND THE SUFFRAGETTES

IT is greatly to be regretted that the Institution of Electrical Engineers should have thought fit to let a portion of a building in Tothill Street of which they are the landlords to the Women's Social and Political Union. The Institution, of course, knew to whom they were letting, and should have known that the Union is the central body organising the "militant suffragette" campaign—in fact, in a statement made at the Annual General Meeting of the Institution of Electrical Engineers last month (but suppressed in the Official Report in the *Journal*), Mr. Robert Hammond, who takes responsibility for the administration of the Tothill Street property on behalf of the Council, regarded it as a good joke that the arrangements had been made with "the suffragettes" for a short-period tenancy. The offices in question are now being used as the temporary centre from which the present destruction of churches, insults to the King, and other disorders are organised, and were raided by the police on Tuesday. We trust that the lease will be terminated by the Institution forthwith.

## MEMBERS AND VISITORS ATTENDING THE I.M.E.A. CONVENTION

(Strictly Copyright.)

THE following is a list of the members and invited guests who had intimated their intention of attending the Convention up to the time of our going to press yesterday. This list is to be taken in no way as "official," but every effort has been made to make it as complete and accurate as possible.

The abbreviation *Ch'n* stands for Chairman of the Electricity Committee, *C'r* for member of Electricity Committee, *E.E.* for Chief Electrical Engineer.

## ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

**T**HE Incorporated Municipal Electrical Association will hold its Nineteenth Annual Convention from Tuesday to Friday next week in Birmingham, Coventry, and Stratford-on-Avon. The headquarters will be at the Grand Hotel, Birmingham, and a time-table of the meeting and visits to works, which include the Summer Lane power station of the Birmingham Corporation, General Electric Co., Belliss and Morcom, Daimler Co., and the Coventry and Worcester Corporation Electricity Works, will be found in our "Arrangements for the Week" column on p. 316. In accordance with our usual custom, we give below portraits and brief biographical notices of the President and the readers of papers, and we also publish descriptions of the features of interest in the works to be visited.

Mr. R. A. CHATTOCK, the President, has been Chief Electrical Engineer to the Birmingham Corporation since 1903, when he resigned a similar position at Bradford to which he was appointed three years previously. At the time he went to Birmingham, the conditions of electric supply were capable of vast reorganisation, and the work of carrying this out has occupied so

in this matter, and for this reason in the past has been a supporter of the I.M.E.A. Bill. It is not improbable that his Presidential Address will make some reference to this question.

Mr. W. A. VIGNOLES, Chief Electrical Engineer to the Grimsby Corporation, was one of the first among central station engineers to realise the importance of systematic advertising and the running of a publicity department. Therefore his Paper on Tuesday on "The Commercial Development of Electrical Supply in Towns of Moderate Size" comes from one who may be termed a pioneer in this branch. His frequent speeches at I.M.E.A. Conventions have always been to the point and invariably impart useful information. The success of his methods are demonstrated by the last accounts of the Grimsby Electricity Department, a much larger profit having been earned than was estimated, notwithstanding the high price of coal and large payments out of revenue for mains and meters. He has been in charge at Grimsby since 1901.

Mr. S. E. FEDDEN, General Manager and Chief Engineer of the Sheffield Corporation Electricity Department, who will read a Paper in Coventry on Wednesday on "The Design and Operation of Modern Boiler-House Plant," is another well-known speaker at I.M.E.A. Conventions. He has been at Sheffield since 1900, and has made a great reputation for the manner in which he has developed the undertaking, particularly in the direction of power supply, in face of the competition of gas supplied in the region of 1s. per thousand cu. ft.

THE PRESIDENT.  
R. A. CHATTOCK.

W. A. VIGNOLES.

S. E. FEDDEN.

J. H. BOWDEN.

much time that Mr. Chattock has had little opportunity for much else. His first step was the design of the Summer Lane power station, which was only completed last year, but the development has been so rapid that a new 100,000-kw. power house is now in hand. Once again Mr. Chattock is responsible for the complete design. His broadmindedness appeals to the electrical contractors of Birmingham, for although he has full wiring powers they are not exercised, he having expressed his entire satisfaction with the work carried out by Birmingham contractors. At the same time Mr. Chattock is prepared to take up the cudgels on behalf of those towns not so favourably situated

Mr. J. H. BOWDEN, Chief Engineer to the Poplar Borough Council, reads a Paper at Stratford-on-Avon on Thursday dealing with the Standardisation of Tariffs, a subject which comes up afresh with every increase of the efficiency of incandescent lamps. Unlike the other authors, Mr. Bowden has never previously read a Paper at an I.M.E.A. Convention, and has seldom spoken. He has given considerable attention to the question of tariffs in recent years, and the Paper may be expected to contain the results of his experience. Mr. Bowden has been Engineer-in-Chief at Poplar since 1904, and has been responsible for the various extensions since that date.

## WORKS TO BE VISITED

## THE SUMMER LANE ELECTRICITY WORKS OF THE BIRMINGHAM CORPORATION

THE electric supply of Birmingham has been carried on by the Corporation since 1900, when the two stations at Dale End and Water Street of the Birmingham Electric Supply Co. were taken over. The load, however, increased so rapidly that it was soon necessary to build an entirely new station, with the result that the Summer Lane Electricity Works, which will be thrown open to inspection on Tuesday, and is also down on the programme to be formally visited on Friday, was opened in 1906, at a site which, although near the centre of the town, is convenient as regards condensing water and canal-borne coal. So rapid has been the continuance of the growth of the load since then that history is about to repeat itself, and yet another new station is in progress at Nechells.

From the Summer Lane station three kinds of supply are given: a three-wire D.C. supply at  $2 \times 220$  volts, a 550-volt tramway supply, and a 5,000-volt three-phase supply to the more

factor of 0.66; they generate at 5,000 volts, 3 phase, 25 cycles. Each is provided with its own exciter, but the small continuous-current turbo sets mentioned above are available for standby excitation purposes. A point of interest in the rows of Belliss engine sets is the way in which the condensers are arranged between the engines, so that any engine can exhaust into the condenser on either side of it. The new turbo sets have, as usual, their own condensing plant under them; the air pumps are of the Edwards type but are steam driven, but the circulating pumps and practically all other auxiliaries in the station are electrically driven.

The boiler-house runs parallel with the engine-room on one side only, so that for the further row of plant rather long steam pipes are required; these pass under the engine-room floor. The boilers—all of the Babcock & Wilcox type—have gradually increased in number as the new generating plant has been put in, and it is interesting to note how in the matter of floor space it has overtaken the generating plant as more and more compact sets have been put in, so that extensions of the boiler-house were required but not of the engine-room. The whole of the stoker shafts and other boiler auxiliaries can be driven either by motors or by standby steam engines, and in the same way both steam and electric feed pumps are provided. All coal is canal borne, and a very ample coal-conveying plant is installed. This plant was supplied by the New Conveyor Co., Ltd. (Smethwick), and its principal feature is a bucket conveyor

THE ENGINE ROOM AT SUMMER LANE, SHOWING ONE OF THE NEW TURBO-ALTERNATORS, WITH THE OLDER RECIPROCATING PLANT IN THE BACKGROUND.

outlying districts. The general arrangement of the engine-room, which is 275 ft. long by 100 ft. wide, is the placing of the continuous-current sets on one side of the room and the alternators on the other. This imposing double row of plant gives a particularly spacious effect. The original main sets on both sides were of 1,500 kw. capacity, with Westinghouse and Dick, Kerr generators, all driven by triple expansion Belliss engines, four in number on the D.C. side, and two in number on the A.C. side. There are also two 500-kw. D.C. Parsons turbo-generators which were removed from Dale End, and three 500-kw. Dick, Kerr alternators driven by Belliss engines. Several further units of the same kind were subsequently added, but in the meantime such was the progress of the steam turbine that, long before the engine-room was full, the installation of reciprocating plant was discontinued. The next extension took the form of an exhaust steam turbine added to one of the latest Belliss-Dick, Kerr alternator sets, another was fitted in so that no extra floor space was required. More recently two 5,000-kw. turbo-alternators, one of which is seen in the illustration, were put in, bringing the total capacity of the station up to 36,500 kw. The small floor space that these occupy for their output relatively to the older plant is very striking. These two sets were supplied by the British Thomson-Houston Co. (Rugby). The turbines are of the six-stage horizontal Curtis type. The alternators are capable of an output of 7,500 k.v.a. at a power

passing over the top of the boiler house for the supply of coal, and on its return journey running underneath for the conveyance of ashes. It is 2,000 ft. in length, and has a capacity of 40 tons per hour. This conveyor receives coal at the canal side from shoots which discharge from a collecting box fed by the belt shown in the illustration, which receives the coal from the barges.

With these vast extensions of plant it became no longer possible to rely only on the canal for cooling of the condensing water, and a group of 12 large cooling towers was accordingly erected. These towers, which were supplied by the Worthington Pump Co., are of the cylindrical steel pattern, and each is capable of dealing with 125,000 gallons of water per hour.

The switchgear is all concentrated at one end of the station, and, considering the various kinds of supply given, is naturally somewhat extensive, although it can hardly be called complicated. Practically the whole equipment is of the British Thomson-Houston Co.'s manufacture. The same general idea is followed as in the engine-room of keeping the continuous-current gear on one side, and the A.C. gear on the other. The continuous-current gear is on a large scale, and provides for both the 550-volt traction supply and the feeders to the 440-volt supply, and it may be mentioned here that any D.C. generator can be run either compound at 550 volts, or shunt at 460 to 520 volts. There is also provision for control of the necessary

feeder boosters and balancers, a battery, the motor-generator, which acts as the connecting link between the traction and lighting bars, so that one can be supplied by the other if

COAL-HANDLING PLANT AT SUMMER LANE.

necessary, and the rotary converters, which in like manner connect the D.C. and A.C. sides of the station. A large number of D.C. outgoing feeders are provided for. Everything, including the changing over of the generators from shunt to compound, is done on the board, so that there are large quantities of heavy cables from the machines to the board. These are taken through a spacious cable subway under the engine-room floor, which is one of the special features of the station. The alternating-current gear is in many ways simpler and presents a fine example of remote-control H.T. oil-switch equipment, with a particularly conveniently-arranged desk-pattern control-board.

of the other substations. The old Water Street Station still contains a certain amount of steam plant, but ultimately the whole generation will be done at Summer Lane and Nechells. The whole undertaking is a monument to the skill and foresight of Mr. R. A. Chattock (City Electrical Engineer), from whose designs the Summer Lane Station was built, and, as President of the I.M.E.A., he may justly be proud in showing his friends round one of the finest stations in the kingdom.

### THE COVENTRY ELECTRICITY WORKS

THE first visit arranged for Wednesday afternoon is to the Electricity Works of the Coventry Corporation, where members will see a station which has been much changed, as its equipment has gradually been increased in output and in which turbo-generators of large size and modern design are gradually displacing the older reciprocating sets. The undertaking, which generates two-phase current only, has many points of interest, and the way in which the cost of generation is declining as the load is increasing reflects great credit upon Mr. George Tough, engineer and manager.

The original rope-driven single-phase plant started up in 1895 has now all been renewed to make room for larger units, and the original engine room, which at one time was filled by plant having a total capacity of 750 kw., at present contains plant totalling 11,000-kw. capacity. In November, 1902, 2-600-k.v.a., 2-phase, 50 cycle, 2,000-volt generators were installed by the British Schuckert Co., and the conversion from a single-phase 87 cycle, to a 2-phase 50-period system, was commenced. These generators are of the flywheel type, running at 125 r.p.m., directly coupled to marine-type engines with self-contained condensing gear by J. & H. McLaren (Leeds). These sets were followed by further sets of 2,600, 2,800, and 1,600 k.v.a., with Schuckert-Siemens and Westinghouse alternators, respectively, all driven by McLaren triple expansion engines similar to those previously installed. The latest stage of development commenced in April, 1910, when a 2,750-k.v.a. 2-phase horizontal Curtis turbo-generator was installed by the British Thomson-

ONE OF THE NEW TURBO-ALTERNATORS AT COVENTRY.

The various public substations, including those in the districts of Aston and Handsworth recently absorbed into the Birmingham area, are, we believe, 14 in number, and contain rotary converters aggregating some 22,000 kw. There are also over 100 substations on the premises of large-power consumers. The former Dale End Station is now entirely a substation, and serves also as a D.C. distributing centre. It contains converting plant of a capacity of 3,000 kw., a number of boosters, and a 7,000-ampere-hour battery. Batteries are also installed in some

Houston Co., Ltd., the machine being designed to give its output at 2,100 volts, and a power factor of 0.8 when running at 1,500 r.p.m. This set was closely followed by two additional turbo-generators of the same type and capacity. The condensing and pumping gear for these machines is of the Workington Pump Co.'s manufacture, and owing to the nearness of water to the surface of the engine room basement, the arrangement is adopted of placing the condenser on the engine room floor alongside each machine, instead of the more usual position

directly beneath the turbines. The exhaust steam had thus to be conveyed to the condensers by overhead exhaust pipes which give the sets an unusual appearance, as shown in the photograph reproduced here. The air and circulating water pumps are electrically driven.

In order to utilise to the fullest extent for cooling purposes the canal on the side of which the works are situated, the circulating water is conveyed from the condensers along a 36-in. steel pipe line to a point situated about 300 yards from the inlet screens. With increasing loads, however, the cooling effects ultimately proved inadequate, and four Worthington steel cooling towers, each dealing with 125,000 gallons per hour, have therefore been installed for this purpose. The pipe was constructed by Messrs. Stewarts and Lloyds, Ltd., and is composed principally of 28-ft. lengths of patent locking bar wrought steel pipes.

The present switchboard, which stands in the same position previously occupied by two other boards, was supplied by the British Westinghouse Co., Ltd., and is of the remote-controlled, mechanically operated type, with the control panels placed in a gallery directly above the granolithic switch cubicles contained in a room on the ground floor. No switching is effected on the neutral conductors, these being permanently connected to earth. An extension to the switchboard has recently been completed, to accommodate additional feeders, and to enable the older board to be converted into a feeder board divided into two sections, and supplied through group switches from the new board, to which the turbo-generators have been connected.

The boiler house contains eight Babcock & Wilcox tube boilers, and four Lancashire boilers, all fitted with Bennis automatic stokers. Local water-borne coal is used, and the deliveries are checked by an automatic weighing machine. The coal to and from this machine is mechanically transported to the various

To give an idea of the magnitude and nature of the load, it may be said that, during the year ended March 14th last, 16,508,338 units were sold, of which no fewer than 14,932,800 were for power. The load factor was 20·4 per cent. Typical load curves show a winter maximum demand of 3,575 kw. and a summer maximum demand of 5,300 kw., but a record load of 9,240 kw. has been observed. The total costs per unit metered for last year (not including capital charges) amounted to 0·717d., of which actual works costs accounted for 0·239d.

### THE WITTON WORKS OF THE GENERAL ELECTRIC CO.

ONE of the most interesting visits during the Convention will be that to the group of works of the General Electric Co., Ltd., at Witton, Birmingham, on Tuesday afternoon, where the Company have their main engineering works for the manufacture of heavy electrical plant, switchgear, arc lamps, &c., the adjoining newer shops for fans, small motors, &c., their conduit factory, their central stores, and the famous carbon works, the only one of its kind in England. Unfortunately, however, the last mentioned, at which important work for the Admiralty is carried on, is not open to visitors.

#### The Witton Engineering Works.

The principal part of this works, which was established in 1900, is the large single shop illustrated here, in which the

ONE OF THE ERECTING BAYS IN THE MAIN SHOP OF THE WITTON WORKS.

bunkers and boiler hoppers by Bennis elevators and distributors. Two Harris-Anderson separators are used for removing grease from the feed water, and a Kennicott softener for treating the canal water are used for making up the "feed" supply. With the exception of the boiler feed pumps, which are Weir's direct-acting steam pumps, the whole of the boiler-house auxiliary gear is electrically driven.

The underground cables in use here are either of the concentric or twin concentric type, paper insulated, and lead covered. Generally these are drawn into single 3-in. earthenware pipes, provided with "Stanford" joints. The low-pressure mains are supplied from a number of static transformer sub-stations stepping down to 200 watts. Large power consumers obtain their supplies from sub-stations erected on their own premises, and the equipment has to be purchased by the consumer before he becomes entitled to the special bulk supply rate. During the year ending March 31st last, 25½ miles of cable were laid, bringing the total length of cable in service up to approximately 140 miles.

whole of the dynamo and large motor work construction is carried on. The machine shop, erecting shop, and winding department all find accommodation in the spacious bays of this large shop, which is 350 ft. long by 210 ft. wide. At the present time a large amount of work is going through, and at almost every point machinery may be seen in course of construction indicating the present trend of heavy electrical engineering practice. Particular interest attaches to the numerous turbo-alternators going through, and there are many details which are worthy of attention, such as the way in which the slots in the rotors are milled separately out of the solid steel bodies, and in the methods adopted for cooling these machines. Efficient ventilation of the stator windings is assured by the slots being made deeper than the coils, so that an empty space is left behind them for the circulation of air. Another unique feature is the use of separate fans, one at each end of the rotor to cool the stator and rotor respectively. Attention should also be called to a group of four 750 kw. rotary converters destined for Southwark, to be used in

conjunction with two 1,500 kw. turbo-alternators for giving D.C. supply. There is a good deal of discussion going on just now as to the relative economy in using geared turbines for this class of works, as is done at the Horseferry Road station at Westminster (see ELECTRICAL ENGINEERING, May 21st, page 279), and it is interesting to find a case where A.C. generation with rotary converters has been decided upon. One of these rotary converters is illustrated here. Another machine worthy of remark is the large continuous-current rolling mill motor, also illustrated, which is for a Lincolnshire steel works. Attention should be drawn to the lubricating system worked by a small chain-driven pump. Some special mining motors will also be seen, with sealing boxes for the terminal connections attached to the frames of the machines. The company's standard practice is to bring out both ends of each winding of the three-phase stators to six terminals, which is a great

750 KW. ROTARY CONVERTER FOR USE IN CONJUNCTION WITH TURBO-ALTERNATOR AT SOUTHWARK.

convenience for locating any damage that may be done to the coils. A special section of the shop is devoted to the manufacture of the "Witton-Kramer" specialties, which include the well-known lifting magnets, made up to 52 inches in diameter, to lift one ton of ore, two tons of pig-iron, or as much as 20 tons of steel, portable drills, and other tools, and a considerable range of travelling hoists and complete telfer equipments. The machine tool bay is equipped with some very fine machines, including very large planers, boring mills, and other special tools driven by individual motors. The large main shop is as full as it can hold with work, and it is not surprising to hear that another large new shop of considerable size is about to be erected parallel to it in the space between it and the fan works.

The power-house, from which the whole of the power for

750 H.P. CONTINUOUS CURRENT ROLLING MILL MOTOR.

driving the group of works is obtained, is situated in a separate building. The most interesting item is a large turbo-generator, which consists of the first D.C. high-speed generator built by the firm, driven by a Belliss turbine. There are also several other reciprocating sets, which bring the total capacity up to 5,000 h.p. Continuous-current motors are employed

throughout the works. Boiler extensions to provide power for the new shops about to be erected are already in hand. Behind the power-house is the dynamo-testing department, which is particularly well equipped for all kinds of tests of machines up to 2,000 kw., and at the time of our preliminary visit the other day some very interesting machinery was being tested, including some pipe-ventilated motors for a cement works, with special provision for preventing oil being sucked through the bearings by the difference of air pressure inside and outside the case. Several Kapp vibrators for the improvement of power factor were also undergoing tests. Adjoining the test house are the painting and packing departments, from which the machines are finally despatched. The company make all their own iron castings in a spacious foundry in a separate building, 335 ft. by 100 ft., at the back, capable of turning out over 60 tons per week.

### The Fan and Small Motor Works

Established in 1912 this forms practically a separate works, and consists of six single story bays, each 300 ft. by 30 ft. It is quite the largest works devoted to this class of work in the country. The first bay contains a magnificent row of presses and notching machines, upon which the whole of the core plate stamping for the main works is done, as well as that for the actual fan motors. Conveniently adjacent in the next bay is the die, jig, and tool-making department, and this, again, serves the whole establishment. The machinery department is at one end of the third bay, with an equipment specially adapted for the production of interchangeable work. Assembling of parts, such as motor frames, is carried out at the other end. Jig work is used wherever possible, and a very complete system of gauging is in operation. The armature and field coils are wound in the next bay, and in this and succeeding bays, one of which is illustrated, the assembling is continued, and complete fans and small motors are turned out. The arrangements for testing both individual armatures and coils, as well as complete fans and motors are extremely complete, and every fan turned out is most thoroughly tested. The last bay of all is largely de-

ASSEMBLING DEPARTMENT IN THE FAN WORKS.

voted to motors for miscellaneous purposes up to about 1½ h.p., including special motors for electric pulley blocks. Among the fans made there are many types, both for continuous and alternating currents, ranging from a diminutive table fan taking only 20 watts, to large ventilating fans for marine purposes. A specially interesting pattern is the Swan ceiling fan with its helical oil grooves, which automatically pump the oil up and prevent it running out of the bearings. In the winding of the armatures for these fans a most interesting machine is used which winds the coils in the slots themselves.

### The Switchgear and Arc Lamp Departments.

These departments are situated on the upper floor of the front and one side of the main engineering works. In the switchgear section a fine white marble board, 45 ft. long, for Cardiff is under construction as well as a good deal of switchgear, which the company has in hand for a contract for complete lighting plant for the town of Ermelo, South Africa. The standard G. E. C. ironclad, interlocked, oil-switch panels will also be examined with interest. A large section of these shops is devoted to the manufacture of motor starters and controllers, for which there is a special light machine shop. Enclosed switches, both for house service purposes and in larger sizes, are made in enormous quantities. Of one particular design of house-service switch in aluminium case as many as 15,000 are made in one year. Another very important part of the works is the adjoining arc lamp department, where in particular the opportunity can be taken to examine the details of the latest patterns of the famous Angold magazine lamp, and the special patterns of globes which have been designed for use with it.

### The Central Stores.

No description of the Witton Works would be complete without a mention of the central stores for finished goods, which are housed in a comparatively new building with three floors each 350 ft. by 50 ft. Here is kept a stock of practically all the company's manufactures except Osram lamps, including the products of the Illeene works, referred to later, as well as articles made at Witton. A vast stock is carried of something like 20,000 different articles, and the concentration of these at one point in a town so centrally situated as Birmingham greatly facilitates both efficient service to the various branch establishments and regulation of the rate of manufacture.

### The Conduit Works.

Beyond the central stores, and not far distant, is the Conduit Works, consisting of three bays, each 200 ft. by 110 ft., and with a capacity of 2,000,000 ft. of conduit per week. There is much of interest in the methods employed. Several kinds of conduit tube are made. What is known as "close joint" conduit is made by bending up flat strips in special machines by a series of rolls. This is done both hot and cold. In the hot process the strips are fed through a muffle fired by crude oil, and the edges turned up and bent over in two operations. The machines used can make any size of tube in this way up to 2-in. diameter. In the cold process used for lighter gauges of material the rolling is performed in four operations. Another class of tube has the joint welded. Here, again, two processes are in use.

### WILLANS & ROBINSON'S VICTORIA WORKS, RUGBY

THESE works will be open to members who desire to see them on Wednesday afternoon, when the Company will convey their guests to Rugby and back from Coventry.

The works were started up in 1897, and have been extended from time to time to cope with an increased volume of work. From 1,000 to 1,100 men are now employed. The leading manufactures consist of steam turbines, Diesel oil engines, condensing plants, and high lift turbo pumps for collieries, waterworks, &c. The foundry is one of the largest in the Midlands, and a quantity of castings are produced there for outside engineering works, as well as all the firm's own castings, which are made from a very high grade of cast iron. The illustration shows a corner of the turbine blading shop. Amongst the turbines to be seen in the foreground are parts of three units of 3,000 kw. each on order for the West Australian Government's Station at Perth, built to the order of Messrs. Merz & McLellan. A large rotor in the background is for a 7,500-kw. turbine for Leeds Corporation. A similar set, but of 8,500-10,000 kw. output, is being built for Sheffield Corporation. Amongst other turbines of interest, and now in the course of construction, attention may also be drawn to a 3,000-kw. machine to run at 3,600 r.p.m. ordered for Regina, in Canada. This is a fair illustration of the modern upward tendency in the speed

PART OF BLADING SHOP AT WILLANS & ROBINSON'S WORKS.

In one the tube is first formed out of strip in the same way as with close-joint tube, and the joint is then closed by passing slowly in a special machine through an acetylene blow-flame. There are several of these welding machines fed by a group of six acetylene generators. In the other or fire welding process the strips are placed in a furnace and drawn out through dies by a chain-draw bench, the last operation closing the joint with a continuous weld. The process is a fascinating one to watch, and requires no little skill on the part of the men at work. A certain amount of brazed tube is also made. An extremely ingenious machine is in use for lining tubes with insulating material, which is stuck on to the inner walls of the tube by a method employing compressed air. Another interesting part is the enamelling department, where tubes are dipped in troughs of black liquid enamel, hung up in frames to drain, and then transferred in batches by overhead runways to the steam-heated drying ovens. A large quantity of conduit fittings are made for which there are extensive punching and machine shops, containing many interesting special machines for making bends, which are bent from short lengths of tube with stout helical springs inside them, and for producing both stamped and cast fittings. All these are also enamelled in special stoves. Watertight cast-iron electric-light fittings are also made in this department. There are, of course, commodious stores, and the whole works strikes one as very conveniently arranged for the progress of the work through it.

output curve; 60 cycles being the standard frequency in Canada, the company have had to get out a special series of patterns for 3,600 r.p.m. turbines to enable us to meet this market's requirements. There will also be a good deal of interest to be seen in the manufactured stores' bay. All parts of machinery are passed into this bay to be checked to gauge, and, wherever the process permits, parts are held in stock to be drawn on as orders demand. The tool room, in which all jigs, gauges, and tools are made and stored, is also particularly worthy of note. The works have always been equipped with a very complete set of gauges. In the fitters' bay end of the erecting shop will be seen a large number of Diesel engine parts, and some steam turbine-driven centrifugal pumps used in connection with condensing plants and also supplied for marine work, and at the other end of the erecting shop a series of complete surface condensers, and parts of ejectors for the Willans-Müller rotary air pump system. Particular interest will centre round the works' Diesel engine. This is a three-cylinder enclosed engine driving a 330-kw. Peebles continuous-current generator, and supplies power for lighting and driving the shops. This engine runs at 187 r.p.m. Since its installation the company have been able to reduce materially their generating costs. These now stand at 0.6 per unit for oil at 80s. per ton, and with full maintenance and depreciation allowance. The cost of fuel is much lower this year, so that they anticipate being able to show a further reduction.

## THE ILEENE WORKS OF THE GENERAL ELECTRIC CO.

**A**LTHOUGH it is possible that time may prevent all the visitors who go over the Witton works from going over the General Electric Co.'s fittings works, no description of the works of the Company in the Birmingham district would be complete without a reference to their Ileene Works in Wheeley's Lane, Edgbaston, Birmingham.

At these works, which are compactly arranged in a building of several floors, adapted from an old brewery, and have been in operation for about three years, over 550 hands are employed in the manufacture of electric light fittings of all sorts, switches, lampholders, and other accessories, as well as electric heating apparatus. These operations were formerly carried out on a smaller scale at the old art metal works in Sherlock Street. The main building, which owing to its clever arrangement is at the same time roomy and compact, consists of a basement, ground floor, and four upper floors, each 8,000 sq. ft. in area, besides stores, offices, and other departments in separate buildings.

In the basement under part of the building there are extensive rough material and other stores, and on the ground floor is the brass and bronze foundry, where ornamental castings for fittings of a very high order are produced. Some of them necessitate the most elaborate patterns, and in the pattern stores are preserved some really fine examples of the wood-carver's art, as well as enormous numbers of the metal patterns from which the castings are usually made. A very complete system of numbering and cataloguing the patterns is in use, and special fittings can very readily be made up by utilising existing patterns. On the same level are also the dipping and plating sheds, and in adjoining sheds are annealing stoves, a grinding shop, and the main boiler.

A very interesting part of the ground floor of the main building is the group of special multiple simultaneous automatic stamping machines for such work as switch covers or lamp-holder bodies, in which successive operations are carried on by a series of stamps side by side, and the work automatically passed on from one to another. On the first floor are shops for the making up of fittings, and the new pattern of "Magnet" electric fire described in *ELECTRICAL ENGINEERING*, May 14th, page 292. On the same floor are the spinning shop, reserve benches for switches and lamp-holders, the pattern-making and chasing shops, the polishing department, and a shop devoted to the manufacture of kettles, toasters, and such articles. The fitting of the heating element to these fires, toasters, kettles, &c., is carried out on the next floor above, where there is also a busy test room, where every piece of heating apparatus is tested before despatch. There is also a small repair shop, and rooms for hot lacquering, cold lacquering, French lacquering, and other finishing processes, besides fitters' shops for the assembly of fittings, fires, &c. It may be noticed that the hot lacquering stoves are all electrically heated. The third floor is devoted mainly to machine shops for fittings, parts, &c., with a tool-makers' shop attached. Owing to the great variety of work, capstan lathes are found preferable to fully automatic machines. The assembling of tumbler switches, &c., is also carried out on this floor, and it may be noted that electrically heated wax pots are used for filling in the holes in the bases. The fourth floor is devoted mainly to the packing and despatching department, so that it will be seen that in general the progress of the work is upward, from the rough material stores in the basement to the packing of the completed articles at the top. There are extensive box stores in the roof. It is difficult to realise when walking through the works how large an amount of work is turned out until it is pointed out that the large heaps of parts or complete goods waiting for removal in each shop represent only a fraction of a day's work, and when taken away will quickly be replaced.

## THE WORKS OF BELLISS AND MORCOM, LTD.

**O**NE of Tuesday's visits will be to the Birmingham works of Belliss and Morcom, Ltd., whose name is so well-known to electrical engineers as manufacturers of the famous Belliss high-speed engine. These are still manufactured in large numbers for the driving of electrical plant, and the firm have also for some time constructed steam turbines, and have more recently turned their attention to Diesel engines and small paraffin engines. Another extensive branch of their activity is the manufacture of air-compressing plant.

Having originated his general engineering business in Ledsam Street, Birmingham, in 1852, the late Mr. G. E. Belliss turned his attention from 1884 onwards, in conjunction with the late

Mr. Alfred Morcom, to marine engines for the propulsion of such fast craft as torpedo boats, launches, &c.; but seeing the great opportunities for applying the experience in high-speed engine construction thus acquired, to the manufacture of special engines for driving electrical plant, they came to specialise more and more in this direction till about 1892, when the marine work was practically discontinued, except as regards engines for auxiliary purposes and the air compressors for torpedo and other work. The rate at which the works has expanded is best shown by mentioning that in 1883 no more than 100 men were employed, while at present the pay roll comprises some 2,000 names.

The older works at Ledsam Street have been entirely remodelled, and are now employed for the manufacture of high-speed steam engines for ship lighting, auxiliary purposes, &c., up to about 90 h.p., the smaller air compressors, and paraffin engines for house lighting, &c., up to 35 h.p. This part of the works has very complete testing arrangements, fully equipped for the steam and electrical side of tests of combined sets. All the machinery is driven electrically, and in the power-house visitors will examine with interest the historic "No. 1" Belliss engine, which has been running regularly since 1889. There are also two 100-kw. sets driven by engines of later make, and, as completing the history, a fine 200-h.p. 4-crank Diesel engine of the vertical 4-cycle pattern running at 250 r.p.m. It has always been the firm's practice to gain experience in their own works with the first engine of a new kind before supplying them in large quantities, but their Diesel engines are now beyond the experimental stage, and a group of five are now under construction for Southend Electricity Works.

All the larger work is done at the newer works a short distance away in Icknield Square, which is a fine example of a spacious, orderly, and well-equipped electrically driven works. Just as the power-house in the older works contains the first high-speed reciprocating Belliss engine for electrical works, and the first Belliss-Diesel engine, so we find in the power-house of the new works the first Belliss live-steam turbine and the first exhaust steam set of 200 kw., as well as two 400-kw. reciprocating sets. The works is driven throughout by 220-volt continuous-current motors, and considerable use is made of compressed-air tools which are supplied by electrically driven compressors at various points. The testing equipment is on a very large scale. A special battery of Babcock & Wilcox boilers, with a separately-fired superheater, is provided, from which steam at any pressure superheat can be obtained. Permanent condensing plant is also provided to which engines and turbines under test can be connected, and provision is made for absorbing the load of electrical generating sets in tank resistances. Engines which are not for driving electrical plant are tested on balanced water brakes of special design. An interesting item in the equipment is a special turbine for balancing turbine rotors under construction.

It is not perhaps generally known that the firm has been experimenting in steam turbine work for some 10 years, and the Belliss turbine reached a high degree of perfection before being placed on the market. They are entirely impulse machines, although both "disc" and "drum" forms are employed. One or two different methods of fixing the blading are employed, according to the proportions of the particular machine. These are simple and ingenious, and give extremely rigid rows of accurately spaced blading. The result of the firm's experience has been that below 1,500 kw. so many advantages are possessed by their reciprocating engines, that the adoption of a turbine is only in exceptional cases good practice. In the case of exhaust steam turbines, however, the limiting size is much lower, and they have standards down to about 200 kw. Before placing a turbine in the market they built several experimental turbines, one of which, of the exhaust steam type, was coupled to the exhaust mains of their shop engines, and has been working daily since the end of 1907. Although only of 200 kw. capacity, the saving on their power-house costs amounts to 1,000 tons of coal per annum, owing to the utilisation of a 28½-in. vacuum. A particular feature of the Belliss turbine is the way in which the whole of the governor gear, which is on the oil-relay principle, is enclosed, and the simplicity of the forced lubrication arrangements, which practically follow the lines of those of the reciprocating engines.

The foundry with its three cupolas can turn out 100 tons of castings per week, and can handle single castings up to 25 tons. Forgings up to 5 cwt. are worked in the smithy, and a large annealing pit and oil-hardening tank is provided. The main machine shop is 280 ft. long, with one 50 ft. and two 25 ft. bays. The equipment of machine tools is very complete, and includes some very large boring mills and planers, with the latest methods of independent electrical drive, and many ingenious small tools for special operations. The main erecting shop is 300 ft. by 50 ft.

One cannot help being very much struck in going through the works by the great care exercised in testing the materials employed for the steel forgings and iron castings used. Tensile, elongation, and impact tests are taken of the steel, and tensile hardness, bending, and shrinkage with every cast. The microscope is also largely used. The cupola practice is scientifically up-to-date, a chemical analysis being taken of all iron and coke

used, as well as a complete series of physical tests of samples taken from the castings and pig iron. Great precautions are also taken to ensure accuracy in the machine shop. The tool room is equipped with a very complete range of jigs and gauges of every description, and the greatest care is exercised in the issue of same to the various departments, each gauge being checked before delivery, on a Whitworth measuring machine, recording up to 8 feet. Micrometer calipers are extensively used in the works, ranging up to 15 in. It is this kind of care and thoroughness that has led to the high reputation that is enjoyed by the firm, and rendered its products so deservedly famous.

### THE DAIMLER WORKS

THE works of the Daimler Motor Co., Ltd., which will also be visited on the Wednesday afternoon, have, apart from the interest of their products, many features which will appeal to electrical engineers as being a large up-to-date factory. The works are divided into two portions; one, electrically-driven, the older works, or Daimler works proper, adjoining the Corporation Electricity Works; and the other, the Radford works, on a large site a few minutes' walk away. The two sites aggregate about 30 acres, and perhaps a better idea of the extent of the works is derived from the fact that over 5,000 men are employed, about equally divided between the two establishments.

Electric driving is, of course, adopted throughout, and the company have their own power plant at the older works, but also purchase electric power from the Coventry Corporation. The generating plant consists of one 350 kw. and two 210 kw. sets, consisting of Cereis-Diesel engines driving Dick, Kerr alternators running at 188 and 150 r.p.m. respectively, and generating at 2,000 volts 50 cycles two-phase. This is the same pressure and frequency as the supply received from the Corporation, which thus serves as a standby as well as a supplementary supply. Either supply can be switched on to any of the circuits by means of the handsome 18-panel Westinghouse switchboard in the engine-room. It may be mentioned here that about  $4\frac{1}{2}$  million units are used per annum, of which about  $2\frac{1}{2}$  million are purchased and the remainder generated by the Diesel sets. Fuel oil is pumped into tanks accommodating a two months' supply from barges on the adjoining canal. Although canal water is used for engine cooling, a Heenan and Froude cooler is employed. An interesting feature is the provision of a spare electrically-driven compressor, which can be used in conjunction with any engine while its own is under repair. Distribution throughout the works is at 2,000 volts by underground cables, and at suitable distributing centres in the shops, transformers are provided stepping down to 200 volts. The transformers are controlled by Berry Skinner enclosed switch fuses, and, together with their low-tension distribution boards, are mounted in wire network cages. The low-tension distribution about the shops is mainly overhead. The distributing centres vary in size, but are mostly for 100 k.v.a. Two-phase induction motors, some of B.T.H. and some of Westinghouse manufacture, are employed. With the exception of about 50 of the larger machine tools group driving with short lengths of shafting is adopted.

The whole of the machine shops, and they are very extensive, are in the older works, and here all engine, gear-box and other chassis parts are machined and the engines assembled and tested; finished engines and other parts are then sent over on motor lorries to the Radford Works, where the chassis of all sizes are assembled. At the Radford Works, where naturally there is not so much machinery, all the power is taken from the Corporation mains. The main part of the works is in the form of a huge single shop, a quarter of a mile long, with three 40 ft. and two 20 ft. bays. Erection of all kinds of chassis, including those for private and commercial vehicles and omnibuses, is done here, and enormous batches may be seen going through. Coach-building is also carried on, on a very large scale. An interesting detail is the method of electrically heating rivets in the car frames in place. A cold rivet is simply placed in the hole, and two terminal blocks, connected by heavy leads to a step-down transformer of very simple construction suspended overhead, are held against its ends. In a few seconds the rivet is hot, when the leads are removed and the rivet closed by a hydraulic rivetter. Electric welding is also employed for coach ironwork, for which a British Insulated and Helsby welder is provided. A special siding runs alongside the main shop, and further on we come to the foundry, where both ordinary and malleable iron castings of very high quality are made. In the same department is a converter for the production of a special variety of high tensile steel for which the company is famous. A small amount of brass casting is also done. Some members will probably be interested in the system employed for heating these large shops. Instead of the now very usual method of distributing hot air in large trunks, there is a distribution of steam to special air heaters situated at convenient points in the roof of the shops, where the air is drawn in by motor-driven fans and heated locally.

### J. H. TUCKER & CO.'S WORKS

AMONG the Birmingham firms who (on any day of the Convention except the Saturday) are inviting members of the I.M.E.A. to visit their works is J. H. Tucker & Co., who have a very modern factory for making their well-known switches and switchgear generally, besides a large variety of electrical accessories. About 500 hands are employed, and the general layout of the works, the good lighting, and fresh air are almost ideal for a factory of this nature. The well-known Tucker switches are completely manufactured here; every part is made at the works except the porcelain bases—even the screws. In fact, more than half a million parts are made per week.

Most of the work is carried out in one large and airy shop, and one is struck by the ingenious automatic tools for some of the purposes. Some of the machines seem almost human in their action. One in particular was making from the solid rod the small pins for holding the handles of the switches. The thread is first cut in a die, the screw is then cut off, lifted against a saw to cut the slot in the end, and then dropped. Another

AUTOMATIC MACHINES IN THE MAIN SHOP.

ingeniously arranged machine cuts the thread for the switch covers after the handle of the switch is riveted on. A tool is applied automatically six times and cuts a comparatively deep thread.

The plating, lacquering, and finishing shops are specially worthy of note for their good ventilation, in particular the dipping shop (where the metal is cleaned before plating), in which the fumes are sucked off immediately above the vats so effectively that no smell at all is noticeable. The firm does all its own cabinet and teak block work, which is by no means trifling, as the manufacture of distribution boards for house wiring is one of its specialities. On galleries running round the main shop the assembling of the switches and other accessories is carried out, and the speed and accuracy of this work is as much a tribute to the good lighting and ventilation as to the nimbleness of the fingers of the girl workers. The works are almost in the open country, but easily accessible by train or tram. Members should take train from either Snow Hill or Moor Street stations, Birmingham, to Tyseley (the journey taking only 12 minutes), and Tucker's Works are then only a few minutes' walk. The firm's telephone number is 101 Acoc's Green, and they would appreciate being notified of intended visits.

**The British Thomson-Houston Co.'s Rugby Works.**—Arrangements are being made by the B.T.H. Co. (as well as by Willans & Robinson) for members to visit their works at Rugby on Wednesday, June 17th, when the Association will meet at Coventry. Those who signify their intention of taking part in this visit will leave Coventry Station at 2.37 p.m., and return in time to catch the 5.35 special train from Coventry to Birmingham. It is proposed on this occasion to include a visit to the incandescent lamp factory of the B.T.H. Co., which is usually closed to visitors. It will be necessary for those wishing to take part in the visit to make application beforehand, as we are informed that no one will be admitted without a ticket.

**Other Works Open to Inspection.**—In addition to the works mentioned above, arrangements are being made for the following works in Coventry to be open to inspection by small parties:—Coventry Ordnance, Triumph Motor-Cycle Works, Coventry Chain Co., and the Coventry Motor Works of the British Thomson-Houston Co. We understand also that Chamberlain & Hookham extend an invitation to delegates to visit their motor works in Birmingham during the Convention in small parties. Early application is necessary to enable arrangements to be made.

## THE WORCESTER ELECTRICITY UNDERTAKING

ON Saturday, June 20th, a visit is arranged to Worcester, where the Powick generating station will be inspected. The Worcester electricity undertaking is interesting as being one of the few in this country where water power is made use of.

The scheme was initiated in 1894, when the Powick station started work with four 125-kw. alternators, two of which were arranged to be driven either by water turbines or steam engines, one by water power only, and one by steam only. The original generators were Mordey Victoria alternators, driven by gearing and ropes from vertical shaft from Victor turbines running on a fall varying from 3 to 10 ft. Clutches permitted of either the turbine gearing or the steam engines being connected to the rope wheel. One set was driven by two small turbines for convenience in handling light loads. The system was single phase at 2,200 volts 100 cycles. A 300-kw. Ferranti steam alternator was added in 1898, but soon this plant became inadequate, and in 1902 a new steam-driven works was opened at Hylton Road in another part of the town, and this originally supplied continuous current only, but A.C. plant was afterwards added to form a connecting link to the old station. The original plant at Hylton Road aggregated 820 kw., and subsequent extensions, including a 1,500-kw. turbo-alternator, inaugurated at the beginning of this year, bring the total plant capacity of both stations up to 3,800 kw. In the meantime, however, all the steam plant had been removed from Powick, which is now a water-power station entirely, and in 1912 the system was changed from single-phase 100 cycles to three-phase 50 cycles, when some of the old alternators at Hylton Road were removed, and one of the old sets at Powick was replaced by a new 250-kw. water turbine with vertical shaft alternator, which will be the most interesting machine that will be inspected. Two motor-generators form the connecting link between the A.C. and D.C. systems, so that the water-power station can feed into the D.C. network when required.

## THE ELECTRIC VEHICLE DEMONSTRATION

CENTRAL station engineers and others who are watching with interest the rapid developments that are taking place in the use of battery-propelled vehicles, will be particularly attracted by the demonstration of electric vehicles which is to take place on Tuesday outside the works of the General Electric Co. at Witton, in which some six or seven firms will be participating.

The Edison battery will be represented on the four cars that are to constitute the exhibit of Edison Accumulators, Ltd. (2 Duke Street, S.W.). These will comprise a half-ton and a two-ton van of a type now familiar in the London streets, the

EDISON ELECTRIC AMBULANCE.

electric ambulance illustrated here, and a small two-seated passenger car. The half-ton van is driven by chain gear through a differential jack shaft by a single series motor controlled by a five-stop controller, has a battery of 60 "A4" cells, and is designed for a maximum speed of 14 m.p.h. and a mileage of 45 to 55 on one charge. The two-ton chassis is somewhat differently arranged; the transmission is by propeller shaft from the single motor to the differential bevel shaft, which drives by side chains. The battery, weighing 9,800 lbs., has a capacity of 300 ampere hours at 65 volts, and is contained in an easily removable cradle. The chassis weight is 5,400 lbs., and a mileage of 45 to 50 miles at 9 to 11 miles per hour is obtainable. The ambulance is designed for 14 miles per hour and a 50 to 60 mile range, and carries a 60 cell 150 ampere-hour battery.

The two-seater with a radius of 60 to 80 miles, runs at speeds up to 21 m.p.h. Another interesting group of vehicles will be the 2½-ton lorry and 5-cwt. delivery van on the Lloyd system exhibited by Mossay & Co., Ltd. (45 Horseferry Road, S.W.). A vehicle similar to the larger-sized one that will be exhibited is illustrated here. Full particulars of these cars were given in a special illustrated article in *ELECTRICAL ENGINEERING*, March 12th, 1914. It will be remembered that the principal feature of the system employed is the use of separate motors, one to drive

2½-TON LLOYD ELECTRIC LORRY.

each of the front wheels through single reduction gearing, arranged so that the whole unit of wheel, motor, and gear turns on the steering pivots. Tudor batteries are employed, and a controller giving a particularly large number of steps, and providing also for regenerative braking, is used. The battery in the 2½-ton chassis is mounted under the centre of the vehicle, and is lifted and lowered by a special hoisting gear on the chassis, but the weight is taken normally by hooks. In the smaller vehicles, the hoisting gear takes the form of jacks on the battery trolley. The 2½-ton chassis has an available platform length of 11 ft. 5 in., and weighs without battery 1 ton 5 cwt. The battery of forty cells, of a capacity of 280 ampere-hours, weighs 17 cwt., and is designed to propel the vehicle forty miles on one charge, with a consumption of 1.25 miles per kw.-hour charge.

A somewhat different method of drive is adopted in the two three-wheeled cars to be shown by the Torpedo Electric Motor Co. (122 Hampstead Road, N.W.), although in this case also the front wheel serves both for driving and steering. These two vehicles will be a half-ton covered van and a four-seated passenger car. The company are also producing a four-wheeled 15-cwt. van, but an example will probably not be ready in time to be shown. The six-pole motor is built into the front wheel, and is arranged so that the field case on which the wheel is

10-CWT. "TORPEDO" THREE-WHEELED LORRY.

mounted and the armature revolve in opposite directions, being coupled together by an epicyclic gear, which has the effect of giving a five to one gear ratio. Speeds up to 15 or 20 m.p.h. can be attained, and the 150 ampere-hour battery gives a radius of action of about 50 miles. The illustration shows the way the whole wheel motor and springs suspensions turn for steering, and the arrangement is such that a particularly good steering lock is obtained. A considerable number of these handy little cars are in use, and they have been found very suitable for the dairy trade. The control is by a pedal and is very conveniently arranged.

Front drive is also employed in a rather different form in the F.R.A.M. vehicles, of which Mr. Conway Jenkins (175 Piccadilly, W.) proposes to show an example. In this system, which is particularly intended for heavy vehicles. The whole of the driving equipment, including motors, control gear, and part of the battery, is contained in a fore carriage pivoted to turn bodily for steering. One motor drives each front wheel through internal spur gearing, and a series parallel control is adopted with provision for electric braking. One of the most interesting features is the way in which the steering gear is interlocked

with the controller, so that a number of cells connected to the motors is made unequal, so that the outer one revolves faster than the inner one when on a curve, giving a differential action and greatly assisting the steering. A tip van on this system is illustrated here, but obviously it is easy to use more than one style of vehicle with alternatively the same fore-carriage. These

F.R.A.M. TIP VAN.

vehicles, which can carry loads up to 5 tons, are largely used for municipal purposes in Paris.

Vehicles are also to be shown by the General Vehicle Co., of New York, who are represented in this country by Mr. E. W. Curtis, of Queen Anne's Mansions, S.W. These will include a half-ton "G. V." parcel van capable of a 50-mile range and a maximum speed of 15 miles per hour, driven by a single series motor through worm gear, and a 2-ton van with canvas-covered body, driven by one motor through double reduction chain gearing. This has a radius of action of 45 miles, and can run at speeds up to 12 miles per hour. Among points of interest on these vehicles are the enclosure of all the wiring in metal conduit and of the control gear in a sheet metal fireproof box. The large van is equipped with an ironclad "Exide" battery. In addition to the above vehicles, it is hoped that a new vehicle will also be sent to the demonstration by W. A. Stevens, Ltd. (26 Victoria Street, S.W.).

An electric carriage which is being driven up to Birmingham to take part in the demonstration by the Krieger Electric Carriage Syndicate, Ltd., 48a Gillingham Street, London, S.W., is illustrated below. Power is obtained from a battery of 50 Naylor cells, which are divided into two batches of 25, and situated at each end of the car. The drive is by two  $3\frac{1}{2}$  h.p. motors, which are coupled to the front wheels through phosphor bronze and steel helical gearing. The control is effected at the steering-wheel, and six running speeds are obtainable. The first four speeds are obtained by running both motors in series

KRIEGER ELECTRIC LANDAULETTE.

with either compound or series field-windings, and utilising either half or full voltage of the battery. The two higher speeds are got by connecting the motors in parallel, and having either series or compound wound fields. Regenerative braking is employed for the front wheels, and the ordinary mechanical band brake for the back wheels. A foot control is provided by which the motors may be cut out of circuit immediately, and cut in again through a rheostat. Electric lighting is used, the lamps being 45 volt with carbon filaments. The normal rating of the battery is 35 amp. hours, although in a case of emergency this may be considerably exceeded. It is intended to make two stops of one hour each for charging at Bedford and Rugby.

**The "Point Fives."**—As already announced in our columns, the special meeting of the "Point Fives" will be held on the evening, Thursday, June 18th, at the Grand Hotel, Birmingham. The time of the meeting is 10 o'clock, and Mr. Allen, of Wolverhampton, will be in the chair. Supper will be served at 3s. 6d. per head. No tickets are required, as the meeting is open to as many as the room will hold. Evening dress is optional.

## TELEVISION

**A DEMONSTRATION** was given recently before the members of the Institution of Automobile Engineers of an apparatus for the electrical transmission of images of moving objects. The property, peculiar to selenium, of altering its electrical resistance on exposure to light, has been utilised before for the more or less imperfect transmission of images of stationary objects. In this apparatus Dr. A. M. Low, the inventor, makes use of the same property. The image to be transmitted is thrown on to a number of selenium cells through a suitable lens. The resistance of each cell varies with the intensity of the light falling upon it. A roller provided with platinum contacts is driven by an alternating current motor backwards and forwards over these cells, making contact with each cell in succession. At the receiving end there is a similarly driven roller moving over a number of contacts, insulated from one another and arranged in the same fashion as the selenium cells. The motors at the receiving and transmitting stations are tuned to run in synchronism, so that the circuit is made between each selenium cell and the corresponding contact in the receiver in rapid succession. The current through each contact will thus be dependant upon the intensity of the light on the corresponding selenium cell. These currents are utilised to control magnetically, the adjustment of a number of steel slats which admit light to squares in the same relative positions as the corresponding cells in the transmitter.

The selenium cells are insulated by thin sheets of mica, and the roller and the cells over which it moves are immersed in paraffin. An induction coil is employed for supplying the transmitting current at a pressure of about 50,000 volts, as this has been found necessary on account of the thin film of paraffin which prevents complete contact between the roller and selenium cells. The total power required is about 80 watts for the sending, and about 50 watts for the receiving apparatus.

In the present stage, however, the pictures obtained are quite crude, as might be expected from the comparatively large squares of which they are composed. The cost of manufacturing the apparatus is considerable, and Dr. Low does not desire to commercialise it until further progress has been made.

## OZONAIR BLEACHING PROCESS

**A NOVEL** application of electricity was seen during a visit organised by Ozonair, Ltd. (96 Victoria Street, London, S.W.), to a wax bleaching plant at Brentford. The plant consists essentially of an electrically-driven blower, an air-cooler, a battery of five ozonisers, and the vessel in which the material is treated. Air is drawn in by the blower, and is discharged through the cooling apparatus, which consists of a water-cooled tank and a CO<sub>2</sub> refrigerator. The cold air now enters the bank of ozonisers through a distributing pipe. These ozonisers have electrodes consisting of flat sheets of wire gauze made of a special alloy, and separated by a dielectric of micanite. High-tension current is supplied from transformers, which have a primary p.d. of 220 volts and a secondary p.d. of from 7,000 to 9,000 volts. A five-point regulator in the primary circuit enables the secondary voltage to be varied as required. The discharge which passes between the electrodes effects the production of considerable quantities of ozone in the air, which is now led to the bottom of the treating vessel, and passes up through the molten wax in fine jets. The ozone present effects the bleaching of the wax. The capacity of the plant inspected was 1 ton of beeswax a day of ten hours, at a total energy consumption of 100 kw. hours.

The installation of this plant has shown very clearly the advantage of using electrical methods for bleaching, in place of the older chemical processes. Whereas the cost of chemicals required for the bleaching of one ton of beeswax in the ordinary way would be about 75s., the cost of electrical energy required to do the same work averages about 5s., so that even after allowing an amount for interest and depreciation of the electrical plant, there is a considerable balance in its favour. Apart from this, the wax bleached electrically is purer and harder than that which has been treated chemically.

**Electrical Child Culture.**—Speaking at a conference of the Child Study Association at Edinburgh, last week, Sir James Crichton-Browne referred to the experiments which had shown that certain forms of electrical stimulus could accelerate the growth of not only plants, but also animals. He sounded a warning against the application of such methods of intensive culture to children, and said that a heavy price might afterwards have to be paid for any immediate spurt of growth thus obtained.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,395.

A three-phase slip ring motor controlled by a reversing type controller, drives a tramcar, and in coming down a steep incline the car runs away and the brakes refuse to act. Can the motor when driven up to or above synchronous speed by the momentum of the runaway car be utilised as an induction generator feeding back to the line, and act as a brake on the car? In what position should the controller be put, i.e., to run the motor in the same direction of rotation or to reverse it, and to get the maximum brake effect as an induction generator should all resistance be cut out of rotor circuit? What is the relation of brake effect and speed of motor under such conditions? What would be the effect of attempting to reverse the motor while the car was running away.—"PUZZLED."

(Replies must be received not later than first post, Thursday, June 18th.)

### ANSWERS TO No. 1,393.

In house-wiring installations consisting only of plain pendants, compare the relative advantages and disadvantages of: (1) looping-in in the ordinary way both at the ceiling roses and switches, or (2) using 3-plate ceiling roses and looping-in only at the ceiling roses.

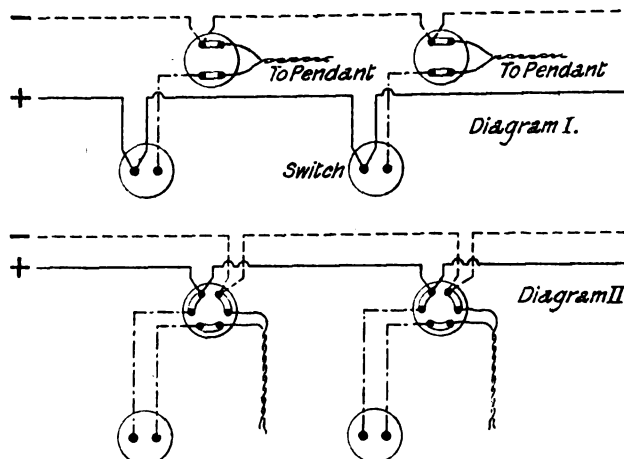

The first award (10s.) is given to "LUPIN" for the following reply:—

In house-wiring installations consisting of single pendants only, I think the use of three-plate ceiling roses unnecessary. With three-plate ceiling roses it is claimed that, owing to the wires to the switches being less, and therefore the size of conduit smaller, a saving is realised. But comparing the two systems, the saving would be little, if any. For house jobs it is advisable to use the same size of conduit for circuits, instead of having different size tube and fittings (reducing). With three-plate roses, even when the switch is off, the full line voltage is at the terminals, which is not what is wanted when new flexible has to be fitted. Also the number of wires at one point, if it is required to loop in different directions, might lead to complications. If it is wanted to go to a "point," and feed back again, it means at least two more wires in the conduit leading to that "point." For this case I think looping in at switches and ordinary ceiling roses is all that is required; it is simpler, and uses the same size of conduit throughout.

The second award (5s.) is made to "J. H. B.," who writes:—

The ordinary method of wiring separately-controlled pendants is shown in Diagram I. Here a double length of main cable has to be used to loop in at the switch, the mains being tapped off the fuse-board. This necessitates conduit or casing equal in cross section to that enclosing the mains, for the switch leads, and also a great cost of cable. With the three-plate ceiling rose system, as shown in Diagram II., instead of looping down the positive main to each switch, and thus using two lengths of full-current carrying capacity

cable, with its corresponding full-sized casing or conduit, the positive and negative mains are taken straight from the fuse-board along the whole length of circuit, leaving wire

to loop into the ceiling rose. The wires going to the switch are just of sufficient capacity to carry the current for the lamps on a single pendant.

By using the ceiling rose with three plates the length of wire used for switch leads is reduced by one-third, also the current carrying capacity of this wire is greatly reduced, the amount depending upon the number of pendants to be put on one circuit. Thus we get a considerable reduction in the area of conduit covering the switch leads, and when a large number of switches are to be used on an installation the cost of wiring is greatly reduced. Of course, the three-plate ceiling roses are more expensive, but this increase is small compared with the saving in wire.

**Electricity Supply in London.**—The Committee of the London electricity supply co.'s engineers which was called together at the time to report on the County of London company's Bill and scheme for remodelling the supply arrangements in London, is now drafting out a scheme of its own, which will, we understand, be shortly considered by the Boards of the various London companies. This will be in a way a reply to Messrs. Merz & McLellan's report to the London County Council, and will have an important bearing on the present situation.

**The San Francisco Electrical Congress.**—Some further information is to hand regarding the Electric Congress which is to be held in connection with the Panama-Pacific Exhibition, 1915. A large number of papers have been promised, and the proceedings are expected to fill 13 volumes dealing with the following subjects: (1) Generation, transmission and distribution; (2) Apparatus design; (3) Electric traction and transportation; (4) Electric power for industrial and domestic use; (5) Lighting and illumination; (6) Protective devices, transients; (7) Electrochemistry and electrometallurgy; (8) Telegraphy and telephony; (9) Electrical instruments and electrical measurements; (10) Central-station economics; (11) Electrophysics; (12) Miscellaneous; (13) General Congress proceedings. The five-dollar membership fee includes the general index and any four volumes. The Congress will be of similar nature to those held at St. Louis in 1904, at Marseilles in 1908, and at Turin in 1911, and a record attendance is expected. The Electrical Congress must not be confused with the other meetings which are to be held about the same time. The respective dates of those of interest to electrical engineers are as follows:—The International Electro-technical Commission meets during the week beginning September 6th, 1915; the International Electrical Congress during the week beginning September 13th; and the International Engineering Congress in the week beginning September 20th.

**Electricity and Aviation.**—According to the *Standard*, the War Office and Admiralty are about to undertake a series of experiments in the direction of the electric driving of aeroplanes. It is stated that a new form of electric battery has come to their notice.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published June 4th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in *italics* indicate communicators of inventions from abroad.

11,370/13. **Manufacture of Steel.** B. T.-H. Co. (*G. E. Co., U.S.A.*). This specification deals with the manufacture of silicon steel having a very low hysteresis action. Silicon steel sheets are assembled in packs and placed between graphite heaters in an electric furnace. The latter is then connected to an evacuator, and the internal pressure reduced to a pressure equal to 2 mm. of mercury, and the temperature is raised to about 1,325° C. All the oxides present in the silicon steel are thus reduced. The duration of the heating process depends upon the amount of steel to be treated, whereas a charge of 500 lbs. requires a run of five hours, 100 lbs. can be treated in about two hours. The resulting product has a peculiarly large granular structure, and low hysteresis factor. Four figures.

11,371/13. **Wireless Transmitters.** G. MARCONI. A wireless transmission system by which continuous streams of oscillations may be produced. Two or more condensers are charged through suitable inductances from a common battery, and are discharged alternately through the primary windings of an induction coil. The secondary terminals of the coil are connected either to the aerial circuit or to a circuit which is in tune with, and coupled to, the aerial circuit. Each condenser discharge circuit must have the same time period as the aerial and intermediate circuit. The period between the commencement of discharge from one condenser and the commencement of discharge from the next condenser should be an exact multiple of the natural time period of the aerial and of the closed discharge circuit. This is effected by the use of disc dischargers which can be rotated at the necessary speed, and an auxiliary or trigger sparking device by means of which small sparks are produced in the discharge gap of the condenser circuits, so as to start the main discharge at the proper moments. Two figures.

12,919/13. **Arc Lamps.** A. H. RAILING and E. A. ANGOLD. A combined spark gap and automatic cut-out for series arc lamp circuits. The spark gap is made smaller than any gap across the insulation in the lamp, and is arranged in series with a resistance. The shunt coil of the cut-out is connected across the lamp terminals. When an abnormal voltage comes on the lamp, the current rushes across the gap, but as it also has to pass through a resistance, the shunt coil is not short-circuited. Hence the cut-out armature is attracted and the lamp is short-circuited and the spark quenched. One figure.

13,135/13. **Braking of Motors.** J. KLINKENBERG. The motor is caused to act as a generator during the braking period. Instead of utilising residual magnetism of the field for this purpose, a relay is provided which, when the motor is acting regeneratively, closes the circuit which excites the field coils of the motor. When the motor is brought to rest, the circuit is automatically opened. A braking resistance is inserted into the circuit to prevent excessive current, by a switch which is automatically closed when the external supply current is cut off. Three figures.

26,708/13. **Watertight Apparatus.** A. E. GRAHAM. This invention is intended to be applied principally to telephonic instruments which are kept in water-tight cases. A circular hole is cut in the case, and a gauze container holding a desiccating agent such as calcium monoxide, is inserted. The container is held in position by being attached at the outer end to a plug which is threaded externally, and can be screwed into place. When necessary, the gauze can be removed for refilling, by unscrewing the plug, and without disturbing the apparatus. Three figures.

## Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** AYRTON [Carbons] 22,319/13.

**Distributing Systems, Insulating Materials, &c.:** B.T.-H. Co. (*G. E. Co., U.S.A.*) [Regulation of distribution systems] 16,054/13; [Insulating material] 16,299/13.

**Dynamos, Motors and Transformers:** ZENK [Commutators] 11,886/13; R. BOSCH [Regulator for dynamo] 26,906/13; SIEMENS-SCHUCKERTWERKE GES. and HULSS [Motor control] 4,308/14.

**Electrometallurgy and Electrochemistry:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Manufacture of boron suboxide] 15,757/13.

**Heating and Cooking:** VENNER [Heating elements] 13,989/13.

**Incandescent Lamps:** JUST [Lamp filaments] 8,956/13; KLEIN [Lamps for advertising] 29,284/13.

**Instruments and Meters:** KELVIN & JAMES WHITE, FIELD and RENFREW [Mariners' compass] 11,503/13; RANKIN and ELECT. POWER STOR. Co. [Recording apparatus for accumulators] 12,527/13; SIEMENS BROS. & Co. and JACOB [Vector calculator] 20,907/13.

**Switchgear, Fuses and Fittings:** MEIKLEJOHN [Wall fittings] 13,588/13; TURNER [Switches] 14,112/13; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Protective devices] 15,550/13; BONHAM [Contact boxes] 19,085/13; DAVIDSON [Switches] 29,821/13; VON HUTSCHLER and ORDON [Switch] 7,562/14.

**Telephony and Telegraphy:** BARON (*Heimann*) [Automatic and semi-automatic telephony] 11,590/13, 11,888/13; AUTOMATIC TELEPHONE MFG. Co. (*Automatic Electric Co.*) [Telephone systems] 11,998/13; INTERNAT. ELECT. Co. (*Akt. Ges. Mix & Genest*) [Microphones] 14,631/13; RICHARDSON [Mouthpiece attachment] 16,964/13; EASTERN TELEGRAPH Co. and JENKINS [Telephone receiver] 16,969/13; SIEMENS BROS. & Co. (*Siemens & Halske Akt. Ges.*) [Signalling arrangements] 2,092/14.

**Traction:** VON KANDO [Electric vehicles] 25,834/13.

**Miscellaneous:** WATKINS [Hair singeing] 10,105/13; WADE (*Leeson*) [Wire coil] 12,168/13; O'KEENAN [Clocks] 23,570/13; POETZELBERGER [Musical instruments] 26,388/13; KRAUS [Separator] 26,802/13; HARTMANN & BRAUN AKT. GES. [Condensers] 4,215/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos, Motors and Transformers:** SOC. ANON. DES AUTOMOBILES ET CYCLES PEUGEOT. [Dynamo machines] 11,089/14; SIEMENS-SCHUCKERTWERKE GES. [Speed regulator] 11,474/14; FÖRSTERSCHE MASCHINENBAU AKT. GES. [Conveyor motor] 11,746/14.

**Incandescent Lamps:** VON BATORKEZ and VERINKHAZ [Manufacture of lamp bulbs] 11,621/14.

**Switchgear, Fuses and Fittings:** SIEMENS-SCHUCKERTWERKE GES. [Fuses] 389/14; OSTERREICHISCHE SIEMENS-SCHUCKERTWERKE [Contacts] 11,410/14; COLLINS [Switchgear] 11,629/14.

**Telephony and Telegraphy:** FLEIJEL [Loading coils for telephony] 8,184/14.

**Traction:** WASSON [Trolley retrievers] 27,163/13, 9,970/14; COLLINS [Control system for vehicles] 11,630/14.

**Miscellaneous:** OSTERREICHISCHE SIEMENS-SCHUCKERTWERKE [Jacquard machinery] 11,808/14; FEYER [Loom driving].

The following Amended Specifications may now be obtained:—  
Incandescent Lamps: J. KREMENEZKY [Manufacture of tungsten wires] 3,112/13.

## Opposition to Grant of Patents

6,421/13, 5,501/14. **Earthenware Insulators.** H. L. DOULTON and H. MORRIS. Opposition to grant of the above Patents has been entered.

## Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

10,637/00. **Variable Resistance Boxes.** A. H. MAYES. The resistance material consists of powdered carbon or similar substance which is contained in the several compartments of a non-conducting box. The partitions consist of copper plates which are connected to the stops on the controller. The resistance is altered by adjusting the pressure on the resistance material. This is done by means of set screws which bear on a pressure plate resting on the loose material. The latter plate must be non-conducting. Five figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** A. ECKSTEIN and A. E. ANGOLD [Clutch feeding mechanism] 3,562/05.

**Distributing Systems, Cables and Wires, &c.:** E. E. E. F. CREIGHTON [Lightning arresters] 26,642/07; W. H. EXLEY and H. LEITNER [Wiring system] 4,066/08.

**Dynamos, Motors and Transformers:** C. E. BONINE [Regulation of dynamos and motors] 28,503/06.

**Ignition:** ELECT. IGNITION Co. and F. H. HALL [Contact breaker] 4,057/06.

**Incandescent Lamps:** A. JUST, F. HANAMAN, H. LANDSBERGER and I. SALZMANN & VEREINIGTE ELECT. GES. [Manufacture of metallic filaments] 4,081/06; E. BÖHM [Lamp bulbs] 3,897/09; B. T.-H. Co. (*G. E. Co., U.S.A.*) [Manufacture of squirted tungsten filaments] 3,951/09; BERGMANN ELEKTRICITÄTS WERKE AKT.-GES. [Filament joints] 9,265/09.

**Traction:** E. H. JOHNSON [Electric brakes] 4,119/07; J. POLKEY [Vehicle lighting] 4,117/09.

**Miscellaneous:** W. BOTTOMLEY (*T. Cahill*) [System of producing and distributing music electrically] 3,666/03, 3,666a/03; C. WEINER [Electro-musical apparatus] 4,011/06.

## ELECTRIC TRACTION NOTES

Until to-day we have not considered it necessary to deal with Monsieur Emile Bachelet's so-called "levitated" railway in this column, which is, as a rule, confined to matters of practical importance, but the endeavour of this hitherto unknown inventor and his associates to secure £90,000 from the general public for the development of an absurd method of electric traction calls for some comment. M. Bachelet has constructed a model of a railway in which magnets placed along the line produce eddy currents in aluminium plates fixed underneath the car, and lift it off the ground; the car is then drawn along by the magnetic attraction of solenoids fitted with automatic make-and-break contacts. The thing may make a pretty toy, but the exhibition and toy rights, which are the only ones possessing some possible value, have already been disposed of, and are not to be the property of the new company for which the £90,000 is asked. Obviously the enormous amount of power which would be required to propel a car in this manner, and the enormous expense of the electro-magnets and solenoids would make any economical practical application for commercial carriage of passengers, goods, or mail matter, an impossibility. No expert opinion on the two patents out for the device, and no independent engineer's report, accompanied the prospectus. Up to the time of going to press we have been unable to ascertain whether the public have been foolish enough to subscribe to a sufficient extent to enable the company to be floated. It is with some surprise, however, that we read in the *Financial Times* that Mr. W. P. Durnall is to act as Consulting Engineer, in conjunction with M. Bachelet.

The accounts of the Lorain surface-contact system at Wolverhampton for last year show that the working costs per car-mile have, as a matter of fact, increased to 6·651d., as against 6·272d. in the previous year. The increase, however, is in a large measure due to an alteration in the assessment of the undertaking from £2,500 to £5,294. The financial result is a net profit of £5,553.

Mr. J. W. Hame, General Manager of the York Corporation Tramways, has reported unfavourably with regard to the adoption of the "pay-as-you-enter" system, in view of the York system being a narrow gauge one.

In connection with the proposed purchase of the Bristol Tramway Co.'s undertaking by the Corporation, Mr. J. M. McElroy, General Manager of the Manchester Corporation Tramways, has been advising the Bristol Corporation. In his report he states that, having studied all means of passenger transportation in the United States, Canada, and the Continent, as well as in the United Kingdom, he has yet to find evidence of the probability or desirability of scrapping tramways and substituting motor omnibuses.

The annual report upon the Dolter surface-contact system at Lincoln shows that the total costs are again lower than those of the Lorain system in Wolverhampton. The comparison of 5·91d. for Lincoln with 6·27d. for Wolverhampton, however, is between 1913-14 at Lincoln and 1912-13 at Wolverhampton. The system continues to work quite satisfactorily, and without incident. The total working costs of 5·91d. per unit are lower than any year except 1908-9.

The Cayenne-Salinas cable is still down, and the Saigon-Bangkok cable is repaired.—On the 4th inst. communication with Siam *via* Moulmein-Raheng and Moulmein-Kanburi was down, and telegrams for Siam were sent *via* Madras-Saigon at rates ruling for that route until the 8th inst., when repairs were effected.—The Commercial Cable Co. has one of its Atlantic links in trouble, and repairs are being taken in hand by their own ship.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The report of the Committee on Wireless Telegraphy Research, appointed by the Postmaster-General, has now been issued. This Committee was formed to consider and report how far and by what methods the State should make provision for research work in the science of wireless telegraphy, and whether any organisation which may be established should include problems connected with ordinary telegraphy and telephony. The report states that, although valuable research work is already being done by the Post Office, the Admiralty, and the War Office, this is for various

reasons necessarily restricted in its scope, and remarks that both in the United States and in Germany more extensive provision for experimental work is made. The Committee considers it desirable to establish a National Telegraphic Research Committee, somewhat on the lines of the Advisory Committee for Aeronautics, to initiate and to control research in matters of general principle which cannot conveniently be investigated in departmental laboratories, to co-ordinate, as far as may be, the work now undertaken by the Post Office, Admiralty, and War Office respectively, in connection with experiment and research in wireless telegraphy, so as to prevent work undertaken by one department overlapping work undertaken by another, and thus secure economy, and to discuss any difficulties arising in practice. The establishment of a research laboratory is recommended, in which research work bearing on the practical needs of the services should be carried out under the guidance of the Committee. The scheme is formulated in some detail. It is proposed that the Permanent Committee include representatives of the Admiralty, the War Office, the Post Office, and the Treasury, as well as the Director of the National Physical Laboratory. Two of the Treasury members would be nominated by the Royal Society, and one by the Institution of Electrical Engineers. The Laboratory would be established at the National Physical Laboratory, with a special premises and staff. The cost of the building and equipment is estimated at £7,300, and the annual expenses at £4,800. The following is the schedule of work proposed:—Improvements in methods of measurement of fundamental electrical quantities under high-frequency conditions. Measurement of efficiency of dielectrics of transmitting condensers used at different voltages, frequencies, and temperatures; quantitative results by which losses can be predetermined. Behaviour of insulating materials at high frequencies and voltages, and best methods of use. Efficiency of different types of receiving condensers. Study of details of design of transmitting and receiving inductances with a view to minimising energy loss. Investigation of crystal and valve detectors under different conditions, and best methods of modifying these to obtain desired characteristics. Effect of variation of coupling between detector circuit and the rest of the receiving circuit. Effect of variation of inductance and capacity in receiving circuit. Methods of mounting and preparing crystals. Methods of amplification of received signals, both acoustic and electrical. Measurements of losses due to brushing from different types of aerials at high frequencies. Measurement of decrement of aerial and earth system. Conductivity of different kinds of soil at high frequencies. Measurement of losses in steel plate earth connections. Measurements on model aerials to assist in design and to predetermine losses. Investigation of "earth antennæ." Investigation of new systems of wireless telegraphy and apparatus employed therein.

Mr. George Franklin presided at the annual meeting of the Constantinople Telephone Co. in Constantinople last week. It was stated that the prospects of the Company are very encouraging, orders having already been received for about 4,800 stations.

The Post Office has taken over the Portsmouth Corporation telephone system at the price of £35,000. This leaves Hull the only municipal telephone system in the country. The Post Office contemplates the erection of a new central exchange, and equipping it with standard apparatus. The Portsmouth licence was obtained in 1901, and had twelve years to run. The purchase price has been agreed upon after a fairly large allowance for depreciation.

**Obituary.**—We regret to announce the death on Saturday, May 30th, of Mr. S. L. Bentley, partner in the firm of H. W. Butler & Co., after only eight days' illness. Mr. Bentley studied in the Polytechnics of Buda-Pesth and Zurich, and also in the Polytechnic School in Paris, and was a member of the Société Internationale des Electriciens. He joined the E.P.S. Co. in 1900, acting as their representative at the Paris Exhibition of that year, and also at the Glasgow International Exhibition of the following year. He was for several years stationed in Glasgow, as their representative for Scotland, subsequently adding to this the north of England. He left them in 1912, and joined Mr. H. W. Butler as partner.

**University College.**—A Heating Studentship tenable in the Faculty of Engineering of University College, London, of the value of £50 a year, together with £11 11s., being the amount of College fees, may be awarded by the Institution of Heating and Ventilating Engineers in July. The student will be required to devote his whole time to research work in heating and ventilating engineering. Further particulars can be obtained from the Secretary of University College, to whom application should be made on or before Saturday, June 20th.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 333. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**ROTARY STRAINER FOR CONDENSING WATER.**—The London Electric Supply Corporation, Ltd. (25a Cockspur Street, London, S.W.), have issued a pamphlet with regard to their patent self-cleaning water strainer for condensing plants and other purposes, which has been in use at the Deptford generating station for the last three and a half years, and is also in use at the L.C.C. tramway generating station, the West Ham electricity works, and the Sheffield electricity works. The Company have found that the strainer is effective at their own station with the very dirty Thames water, and are now manufacturing similar strainers for use elsewhere, in the ordinary way of business. Illustrated descriptions of the strainer appeared in our columns of May 11th, 1911, and June 12th, 1913.

**WIRELESS TELEGRAPHY.**—A new catalogue dealing with apparatus on the quenched spark system for ships has been issued by Siemens Brothers & Co., Ltd. (Woolwich). We understand that this system is now installed on over 100 British vessels. Particulars of a number of these installations are given in the list. The standard ship sets range from the little launch outfit of 0.3 kw. with a guaranteed range of 18 to 30 miles, to the 5 kw. equipment for liners, of a guaranteed range of 280 to 550 miles. Some interesting figures of tests of two sets guaranteed at 300 miles at night show that communication has frequently been established over 1,400 to 1,700 miles. The use of the pamphlet is enhanced by the inclusion of all the important regulations regarding wireless telegraphy by the recent committee for safety of life at sea. Full illustrated descriptions are contained of the different types of equipment on the Siemens-Telefunken system.

**EDISON ACCUMULATORS.**—The constructional features of the Edison nickel-iron alkaline storage battery, together with interesting information as to the remarkable results of tests of its mechanical and electrical strength, are treated in a new booklet from Edison Accumulators, Ltd., Edison Building, 2 and 3 Duke Street, Piccadilly, S.W. The cells are now made in nine different sizes, ranging from 50 to 600 watt-hours capacity. The weight of the largest of these cells is 45 lb.

**CASCADE MOTORS.**—A detailed price list of every size and variety of the Hunt patent "Cascade" single-speed induction motors without sliprings is to hand from Sandicroft, Ltd. (Chester).

### INDIRECT LIGHTING

**EXAMPLES** of indirect lighting by suspended bowl fittings as developed by the British Thomson-Houston Co., are familiar to our readers. The firm have now sent us some particulars of recent installations where indirect illumination is effected entirely without suspended fittings. One case is

CHURCH LIGHTED BY INDIRECT ILLUMINATION.

a drawing-room lighted by one of their table standards with the upturned reflector concealed in the shade. Another case is a bank in which the reflectors are in troughs on the top of screens, while the third, of which an illustration is given here, is a church which happens to have a white ceiling, and is very effectively lighted from the cornice.

### A WATERTIGHT PULL SWITCH FITTING

THE illustration shows a special fitting which has been designed for factory installations by Simplex Conduits,

Ltd., Garrison Lane, Birmingham, and wherever installed found to be most convenient and suitable for the severe conditions in this class of work. It is designed to provide a convenient form of pull switch, and consists of a specially watertight box with 5-ampere standard type of switch fitted inside, operated externally by a lever and chain. The movement is similar to that in the Company's standard form of watertight switch, and gives a very quick and independent break. The dome cover, as will be seen from the illustration, is fitted with a standard type of watertight lamp-holder, so that in this case the light would be actually on the ceiling; but where required the fitting can be provided with any length of tubing drop, so as to lengthen the distance between the light and the ceiling.

### SEA FRONT ILLUMINATION BY METAL FILAMENT LAMPS

A LARGE installation of Pope "Elasta" British-made wire lamps has recently been made at Hastings, where the whole of the band stand and the front is illuminated with 4,000 of these lamps. The excellent effect produced at night

HASTINGS SEA FRONT AT NIGHT.

is seen by the photograph reproduced here. In spite of the exposed position in which the lamps are burning, the fact that they have been running for some considerable time with practically no failures speaks highly for their durability.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Antwerp.**—The Council requires a supply of armoured cable.

**Australia.**—Rotary-converters and frequency changers are required in connection with the electrification of the Melbourne suburban railways. Consulting engineers, Merz & McLellan, 32 Victoria Street, S.W. July 6th. (See advertisement on another page.)

**Bexley.**—A Local Government Board inquiry was held last week concerning a loan of £8,000, made up as follows:—Mains, services, and transformers, £2,500; generating plant, £5,500. There was opposition to the proposal by the local Traders' Association so far as the expenditure on new generating plant is concerned, the argument being that it would be more profitable for the Council to purchase further electrical energy in bulk. It was pointed out, however, on behalf of the Council, that although the Woolwich Borough Council had offered to give a supply in bulk, there were technical difficulties in the way of taking it, whilst further, the supply would not be available during the ensuing winter, when it would be needed in Bexley. At present there is not only no spare, but insufficient plant with all sets running, to meet the maximum demand.

**Bolton.**—Converting plant and sub-station switchgear. Borough Electrical Engineer. July 9th. (See advertisement on another page.)

**Farham.**—New cables and transformer.

**Farnworth.**—The Council is applying for sanction to a loan of £1,500 for a three years' requirement of cables.

**Hereford.**—Loans of £530 for new plant, £500 for a new chimney, and £240 for mains, are to be applied for.

**Irvine (N.B.).**—An agreement is to be signed with the Kilmarnock Corporation for a supply of electrical energy in bulk.

**Manchester.**—Transformers, motors, meters, and starting switches. Chief Electrical Engineer. June 26th. (See advertisement on another page.)

**Nairobi.**—A new issue of capital is to be made by the Nairobi Electric Power & Lighting Co. in order to provide for additional generating plant.

**Pickering.**—An agreement for the supply of electrical energy by the Yorkshire Electric Power Co. has been sealed.

**Stalybridge.**—The Joint Board requires a twelve months' supply of various stores for the electricity and tramways department.

**Stretford.**—Lighting battery, booster, and switchboard. Borough Electrical Engineer. June 15th.

**Sunderland.**—A loan of £12,000 is to be taken up for additional generating plant and switchgear.

**Sydney.**—The Municipal Council requires a supply of 33,000-volt insulators; also two coal conveyors with motors, &c. City Electrical Engineer, Queen Victoria Markets, Sydney, N.S.W. July 20th. Further particulars at 78 Basinghall Street, E.C.

**Teignmouth.**—Negotiations are proceeding between the Council and Dr. J. A. Purves, of Exeter, who expects to be able to supply the district within twelve months.

**West Ham.**—A Local Government Board inquiry was held last week concerning a loan of £6,706 for electrical extensions.

**Worcester.**—The Electricity Committee recommends application being made to the L.G.B. for sanction to the following loans:—Mains in conduits, £2,500; mains direct in ground, £1,000; overhead mains, £500; transformers, £750; sub-station equipment, £500.

### Wiring

**Antwerp.**—Electric lighting of two sheds at the Canal Dock.

**Christchurch.**—Electric lighting of workhouse, infirmary, &c.

**Guildford.**—New telephone exchange. H.M. Office of Works, London.

**Leeds.**—Lighting, bells, and telephone installation at the Grange Hostel, Becketts Park, Headingley. Secretary, Education Department. June 17th.

**London.**—Public offices extension, Westminster. H.M. Office of Works. June 30th. (See advertisement on another page.)

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Blackburn.**—Mill extensions, Moorgate Street. E. Hamer.

**Cambridge.**—Children's Home in Ross Street.

**Crewe.**—New shops. F. Denson.

**Dover.**—New County School for Boys. Kent Education Committee, Maidstone.

**Gillingham.**—New swimming baths.

**Ilkeston.**—Cinematograph theatre.

**Lancaster.**—New school.

**Luton.**—New school.

**Norwich.**—Extensions of municipal offices (£12,800).

**Wigan.**—High School for Girls. Architects, W. C. Ralph & Sons.

**Yarmouth.**—New school.

### Miscellaneous

**Lisnaskea.**—A Local Government Board inquiry has been held with regard to a loan for the purpose of public lighting.

**London: Metropolitan Asylums Board.**—Telephone and bell installation at Orchard Hospital, near Dartford. Engineer to Board, Victoria Embankment. June 17th.

**Watford.**—A report is being prepared upon improving the lighting of a portion of the High Street.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Bacup.**—The tender of Messrs. W. T. Glover & Co. has been accepted for supplying and laying cable.

**Cardiff.**—The following tenders have been accepted:—Steampipes, &c., Babcock & Wilcox; power-station switchgear, British Westinghouse Co.; transformers, Siemens Bros. & Co.

**York.**—The tender of the General Cable Manufacturing Co. at £6,357 13s. has been accepted for high- and low-tension cable.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**British Electrical Federation.**—The summary of statistics for 1913 of the companies forming this Federation shows that there was a net revenue, before providing debenture interest, reserves and dividends, of £1,281,698. The debenture interest and dividends paid for the year amounted to £858,533, and the reserves, including the addition of £407,863 for the year 1913, now stand at £2,176,599. The number of route miles worked by the federated tramways and light railways is now 429.77, and the capacity of plant installed for electric supply, excluding purely traction stations, is 38,572 kw. There are now some 60 companies in the Federation.

**Birmingham District Power & Traction Co.**—An improvement in both the traction and lighting sections of this company's business was reported at the annual meeting last week. The whole of the lighting undertaking, however, has now been sold to the Shropshire, Worcestershire & Staffordshire Electric Power Co., and in future the Birmingham Company will be a holding company in the Power Company.

**Nairobi Electric Power & Lighting Co.**—Negotiations have been completed with the Government for the extension of the company's concession from 25 to 50 years, and the grant of important falls on the Thika River for the generation of electricity.

**Low-voltage Half-watt Lamps.**—The low-voltage half-watt lamps, referred to in our issue of May 28th, for use with small transformers, are now listed in Germany in five sizes: 50 c.p. lamps are made for 14 volts only, and 100 and 200 c.p. for 14 or 25 volts. The price of the 50 c.p. lamp (which consumes 28 watts) is only 1.75 marks, plus 0.20 mark lamp tax, on the German market; the 100 c.p. lamp costs 2.50 marks, plus 0.40 mark tax; and the 200 c.p. lamp 4.50 marks, plus 0.60 mark tax. The lamp-holder transformers for the 14 volt 50 c.p. lamps are stated to have an efficiency of 83 per cent., and cost from 9 to 10 marks.

## LOCAL NOTES

**Bolton: Electricity Profits and Rate Aid.**—A motion at the last meeting of the Corporation to move back a recommendation of the Electricity Committee allocating £2,000 from electricity profits in relief of rates was defeated. Councillor Peters, who moved the reference back, argued that the depreciation and renewal fund is not as large as it should be, but there was a big majority in favour of relieving the rates, as suggested by the Committee.

**Cleckheaton: Position of Electricity Undertaking.**—The municipal electricity undertaking has entailed some loss since its inception, and the question of dealing with it has been given some consideration from time to time. At the last meeting of the Council the newly-elected Chairman of the Electricity Committee made a definite statement that the Council has decided not to part with the undertaking in any circumstances.

**Croydon: Electricity Accounts.**—There was a net profit of £1,877 upon the electricity undertaking last year. This result, however, is obtained after charging £8,206 to revenue, the greater portion of which is in the nature of capital. The net profit has been credited to appropriation account, which now stands at £2,284, and this amount it is recommended shall be transferred to reserve and renewals fund.

**Dundee: Excessive Rating of Electricity Department.**—Speaking at the last meeting of the Corporation, the Convener of the Electricity Department pointed out that the electricity undertaking is far more handicapped in the matter of rating than any other of the municipal departments. The Tramway Department, with an income of £69,000, pays only £1,900 per annum in rates, and the Gas Department, with an income of £158,000, pays £5,800 per annum, whereas the Electricity Department, with an income of £61,000, pays no less than £6,500 per annum. The difference is accounted for by the fact that the other departments only pay 25 per cent. on their rails and pipes respectively, whereas the Electricity Department has to pay the full value on all cables.

**Electricity Records.**—The revenue from the Electricity Department last year was £58,783, an increase of nearly £5,500 over the previous twelve months. The net profit amounted to £5,150, but the deficit on the Broughty Ferry Works reduced it to £3,507. The number of units sold increased by two millions.

**Edinburgh: Reduced Cost of Public Lighting.**—The Electric Lighting Committee recommends the Corporation to reduce the charge for public lighting from £9 to £7 10s. per annum.

**Leigh (Lancs.): Electricity Accounts.**—The number of units sold last year shows an increase of 22 per cent. over the previous twelve months. With regard to the new scheme now in hand, Mr. H. R. Hooper, the L.G.B. Inspector, at the recent inquiry, suggested that a more suitable site should be found for the generating station in order to supply at the lowest possible price the very considerable demand for cheap power which exists in the district. The attention of the Committee is drawn to this matter by the Borough Electrical Engineer in his report. The financial result shows a net profit of £1,154, against £1,080 in the previous twelve months. At the same time, the average price has dropped from 2.06d. to 1.94d. per unit.

**Lytham: Bulk Supply.**—The Local Government Board states that it is unable to deal with the Council's application for sanction to a loan for electric lighting until the St. Anne's Council has obtained the necessary powers enabling them to give the proposed supply in Lytham.

**Manchester: Tour of Inspection.**—The Chairman and Deputy Chairman of the Electricity Committee, together with Mr. S. L. Pearce, the Electrical Engineer, have been authorised to visit Paris, Berlin, a number of American cities, and Montreal, in Canada, to inspect the large generating stations there, and acquaint themselves with the general conditions of extra high-voltage transmission systems abroad.

**West Bromwich: Low Electricity Profits.**—In drawing attention to the fact that the net profit on the electricity undertaking last year was only about £30, compared with a profit exceeding four figures in the previous twelve months, the Borough Electrical Engineer points out that this is mainly due to the increased price of coal, which now stands at 8s. 2d. per ton, against 5s. 3d. A higher-grade fuel was purchased under the last contracts, but the results have not justified its continuance. In addition, the rates and taxes

have increased by £250. At the same time, the opinion is expressed that the rates charged for lighting and power purposes are too low, but that if the redemption of borrowed capital could be continued at 4½ per cent. per annum, and a small balance shown on the right side, the financial position ought to be regarded as reasonably sound.

## APPOINTMENTS AND PERSONAL NOTES

At an Extraordinary Meeting of the Council of the British Electrical and Allied Manufacturers' Association on Monday, the following resolution was passed:—

Resolved that the Council of this Association, in meeting assembled this 8th day of June, 1914, deplore the untimely death of their late Chairman, A. Bruce Anderson, who perished at the sinking of the *Empress of Ireland* in the St. Lawrence River, on the 29th of May, and desire to place on record not only the loss of the chief executive officer of the Association, but also the loss of a personal friend; and that a copy of this Resolution be sent to Mrs. Anderson with an expression of their deepest sympathy for her in her sad bereavement.

The Council of the Royal Society of Arts has awarded the Albert Medal for this year to Mr. G. Marconi, for his services in the development and practical application of wireless telegraphy.

Mr. F. H. Whysall, Resident Engineer at the Bloom Street and Dickinson Street Works of the Manchester Corporation, has been appointed Borough Electrical Engineer at Greenock in succession to Mr. J. A. Robertson, who a short time ago was appointed Chief Electrical Engineer to the Salford Corporation.

The Barnstaple Electric Lighting Committee recommends an increase in the salary of the Borough Electrical Engineer, Mr. J. W. Hadfield, from £200 to £225 per annum.

Mr. T. Hollins, Assistant Mains Superintendent at Watford, has resigned on receiving an appointment elsewhere.

Mr. Percy Taylor, an Assistant in the Darwen Corporation Electricity Department, has received an increase in his salary of from £91 to £104 per annum.

The salaries of Mr. T. Keenlyside and Mr. Hubert Simpson, Charge Engineers at the Crewe Electricity Works, are to be increased from £150 to £165, and from £100 to £110 per annum, respectively.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £64 5s. to £64 15s. (Last week, £65 to £65 10s.)

**H. W. Butler & Co.**—We are informed by Mr. H. W. Butler (Craven House, Kingsway, W.C.) that since the death of his partner, Mr. S. L. Bentley, referred to in another column, arrangements have been made for the business to be carried on as heretofore.

**Holidays.**—Messrs. J. H. Tucker & Co.'s Works at King's Road, Hay Mills, Birmingham, will be closed on Saturday, the 20th inst., for the annual works trip to Blackpool.

## BLAKE &amp; INSULATING STAPLES

Write for Samples and Prices.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

THE Annual Convention of the Incorporated Municipal Electrical Association opened at Birmingham on Tuesday, and we publish a report of the first two days' proceedings. A fuller report on the discussion at Coventry yesterday will appear in our next issue, together with Thursday's and Friday's proceedings. Between 350 and 400 members and visitors took part in the meeting. A list of those who had previously intimated their intention of coming was published in our last issue, and several more (including Dr. Ferranti and Mr. Robert Hammond) made up their minds to come at the last moment.

In his Presidential Address Mr. Chattock, Birmingham, made interesting comments with regard to the Model General Conditions of Contract, the I.M.E.A. Bill, the Electrical Vehicle Committee, and the death of the I.E.E. Industrial Committee, and made a suggestion for combined control of municipal gas and electricity undertakings. He then outlined a proposal for the centralisation of electricity supply, suggesting the possibility of a scheme under which it would eventually be possible to obtain, "at one rock-bottom price," a supply of electrical energy, for any purpose whatsoever. (Page 337.)

Mr. W. A. VIGNOLES (Grimsby) followed with some voluminous "notes" on the commercial development of supply in towns of moderate size. The Paper was, however, only read in abstract. The first part dealt chiefly with business-getting. Grimsby gives free advice to prospective consumers, and draws up a detailed specification and superintends the work at 2½ per cent. Hire-purchase of wiring has been well

developed, and the Corporation assists the contractors in financing such arrangements: Mr. Vignoles considered hire and hire-purchase powers vital, and recommended that if it would assist all municipalities to get these, the powers for wiring and selling should be dropped out of the I.M.E.A. Bill. In this he was supported by Mr. E. E. Hoadley (Maidstone), and it does not seem improbable that the matter will be raised at the Annual General Meeting to-morrow, together with the question of the establishment of a new Publicity Committee by the Association. Mr. Vignoles and Mr. F. Ayton (Ipswich) were strongly in favour of this. Mr. Vignoles was luke-warm with regard to the value of showrooms, and Mr. A. C. Cramb (Croydon) took a directly opposite view. The suggestion in the Paper that the reserve fund should be invested in the undertaking was not criticised, and the latter parts of the Paper dealing with financial control and the calculation of costs to arrive at an equitable tariff were hardly discussed. Much of the discussion centred around the evergreen question as to whether profits should be allocated to relief of rates. (Pages 340 and 347.)

Mr. S. E. FEDDEN's Paper yesterday, on the Design and Operation of Modern Boiler-House Plant, was based on his experience at Sheffield. It dealt particularly with the question of the disposal of ashes, the storage of coal, mechanical stokers, and live steam feed-water heaters, and it concluded with a threat of new conditions of high super-heat under which a dull red gas would be passed through the steam pipes and valves. (Page 343.)

IN connection with the visit of the I.M.E.A. to the Witton Works of the General Electric Co. a preliminary Press inspection was held last Monday, at which a large party went over the works described in our last issue, as well as the carbon works. (Page 345.)

THE motor vehicle parade at Birmingham was a great success; several of the cars had travelled down by road. (Page 346.)

AT the Annual Dinner a speech made by Dr. Ferranti clearly indicated that he was most antagonistic to the policy of the Institution of Electrical Engineers which resulted in the dissolution of the Industrial Committee. (Page 346.)

A BRIEF telegraphic report of yesterday's discussion on Mr. Fedden's paper appears on page 348.

THE poll of the citizens has resulted in favour of the purchase of the Bristol tramways by the Corporation. (Page 348.)

AN experimental wireless telephone conversation from the Eiffel Tower has been overheard by an amateur in England. (Page 348.)

THE arrangement of starting connections for single-phase induction motors to obtain maximum starting

torque are discussed in our Questions and Answers columns. (Page 349.)

A METHOD of rendering tungsten ductile by the addition of a small quantity of another metal is described in one of the specifications published last week.—A patent for the control of electric clocks expires this week after a life of fourteen years. (Page 350.)

In our Trade section are particulars of a large switch-gear contract and descriptions of some new conduit fittings, and a new electric motor-car horn. (Pages 351 and 352.)

TENDERS are invited for five 1,500-kw. rotary converters and transformers by the L.C.C.; switchgear for New Zealand; tramway stores at Rotherham. (Page 353.)

THE tender of the British Westinghouse Co. for a 5,000-kw. turbo-alternator at Salford has been accepted. (Page 353.)

THE *locus standi* of the Metropolitan Electric Supply Co. in objecting to the granting of powers for electric supply to the Brentford Gas Co. has been disallowed.—Considerable developments are taking place in the power load at Manchester. (Page 354.)

A COMPANY is being formed for the manufacture of coalite in Yorkshire. The surplus gas will be used for generating electrical energy. (Page 354.)

**The 15,000-k.w. Turbo-Alternator at Manchester.**—By an unfortunate error it was stated in an article last week, on p. 317, that the steam consumption of the new 15,000-kw. turbo-alternator at Manchester was 16.35 lb. of steam per kw.-hour at full load, with a steam temperature of 330° F. This should have been 13.65 lb. for a steam temperature of 590° F.

**The Paris Disasters.**—In connection with the extraordinary subsidences which took place on Monday in the streets of Paris as a result of the almost unprecedented storms, considerable damage has been done to the cable systems both of the electricity supply and telephones, particularly in the St. Lazare district, where the services were entirely suspended. In some places the tunnels of the Metropolitan electric railway have collapsed.

## ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 18TH.

*Incorporated Municipal Electrical Association.*

10.30 a.m. Birmingham Convention. Meeting at Memorial Lecture Room. "The Standardisation of Tariffs," by J. H. Bowden.

2.30 p.m. Trip to Warwick Castle.

8.30 p.m. Fête and Concert at Botanical Gardens. "Point Fives."

10 p.m. Meeting and Supper at Grand Hotel.

FRIDAY, JUNE 19TH.

*Incorporated Municipal Electrical Association.*

10 a.m. Birmingham Convention. Annual General Meeting at Midland Institute.

2.30 p.m. Visit to Summer Lane Power Station.

8 p.m. Cinderella Dance at Grand Hotel.

SATURDAY, JUNE 20TH.

*Incorporated Municipal Electrical Association.*

10 a.m. Birmingham Convention. Visit to Worcester.

THURSDAY, JUNE 25TH.

*Institution of Electrical Engineers.*

9 p.m. Conversazione at Natural History Museum, Cromwell Road, S.W.

## The London Electrical Engineers.

Headquarters (46 Regency Street, S.W.), open Sats. till noon.

Rating Exam. for all Co.'s from 7 to 8.30 p.m. on Wednesday.

(TO-DAY) THURSDAY, JUNE 18TH, C. Co., FRIDAY, JUNE 19TH.

D. Co., SATURDAY, JUNE 20TH, Annual Course of Musketry, all Companies. Purfleet. MONDAY, JUNE 22ND, A. Co., TUESDAY, JUNE 23RD, B. Co., Advance Party for Berchaven Camp parade at Hd. Qrs., 12 noon.

**Obituary.**—The death is announced of Sir Edward White, who was Chairman of the London County Council a few years ago. Prior to that Sir Edward had been Chairman of the Highways Committee, and as a member of the Council for St. Marylebone had also taken a considerable interest in the Marylebone electric lighting undertaking. We believe we are right in saying that although Sir Edward White was not an advocate of municipal trading, he nevertheless took the commonsense view that in Marylebone, having purchased the undertaking, it was the duty of everyone connected with the Council to do their best to develop it to the utmost extent, and not to put artificial obstacles in its way.

THE LIGHTER SIDE OF THE I.M.E.A. CONVENTION.

FAIR VISITOR: Do please show me a squirrel-cage motor; I do love the little animals, and have brought some nuts for them.

Dr. R—g is left thinking for a suitable reply.

## ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

### PRESIDENTIAL ADDRESS \*

By R. A. CHATTOCK (*Chief Electrical Engineer, Birmingham.*)

THERE are several points on which I wish to touch before coming to the main portion of my address.

#### Model General Conditions.

It is a matter of regret that the contentious clauses have not yet been agreed between this Association and the British Electrical and Allied Manufacturers' Association. The issue of model general conditions by the Institution of Electrical Engineers without the approval of our Association, I feel, is the direct result of the strong opposition manifested by some of the members at the special meeting held in July last. The result is that these Institution model conditions which are at variance with our ideas in many respects, are now being put forward by manufacturers with the authority of the Institution behind them, and buyers are being obliged to accept them without much hope of negotiating alterations in them. I cannot help feeling that a very different result, and one more favourable to us, would have been obtained if members of this Association had adopted the carefully-considered recommendations of the Council twelve months ago, or possibly varied them to only a small extent, and allowed the negotiations with the manufacturers to go on with a view to an amicable settlement of points on which there was a difference between the two Associations.

As it is, the Council have discussed the contentious clauses and the suggestions made at the meeting in July last, with the Association of Municipal Corporations. This Association promised to take the matter in hand and draft clauses in legal terms which were then to be submitted to our Association. We have been waiting now for many months for this draft, and I fear that now, when it does come, it will be too late to have any real effect, in view of the model conditions that have now been issued by the Institution of Electrical Engineers.

#### Electric Lighting Bill, 1914

Everything has been done to try and get this Bill into Parliament. Negotiations were opened up with the Electrical Contractors' Association to try and get them to withdraw their opposition, in order that the Bill might go through unopposed. It was ascertained that many of the contractors were in favour of withdrawing opposition, and at one time it was even understood that this would be done. Subsequently, however, much to my disappointment, and, I think, of all the members of our Council, the opposition element in the Contractors' Association was successful, probably due to the action of those who are opposed to wiring being carried out by municipal supply authorities under any circumstances whatever.

Let us examine the position which would arise if these powers were obtained and exercised, because I believe the contractors exaggerate the quantity of work that it would be possible for a municipality to undertake. First of all, we seek these powers not for the purpose of securing more trade, but to ensure good work, especially in the cheaper classes of installations. The expensive work in hotels and good-class business houses and residences, which is well paid for, is, as a rule, well done. Moreover, there is the wiring work for telephones and bells which the contractors must obtain, because the municipality has no power to do it and does not seek such powers, with the result that a customer will probably prefer to place the whole order with one person instead of two. In addition, the contractor can calculate the profit on the whole combined order, and he could probably successfully compete in price with the municipality. With the cheaper work, the case is entirely different, the margin of profit is so small that the quality of the work often suffers, and the men who do it, as a rule, are not worth "going for" if trouble results. It is this jerry work that we want to eliminate. If we obtain the powers we seek, we shall be able to put to the contractors who are at fault that they must do good work or we will do the work ourselves. There is surely nothing to be alarmed at in this.

The opinion has been expressed that some of the supply engineers are inclined to be unfriendly towards the contractors, and that on this account it would be detrimental to the contractors to agree to wiring being carried out by a supply authority. There may, of course, be undertakings where things do not run smoothly between the engineer and the contractors, but I venture to think that these are few and far between and should not govern the general policy of an important Association such as that of the contractors.

In any case, I maintain that the idiosyncrasies of a few

engineers, and possibly also of a few contractors, should not be allowed to interfere with the well-considered policy of our Association in putting forward a scheme that all supply engineers, and, I venture to believe, all broad-minded contractors, consider to be in the general interests of the industry. Supply engineers, in order to hold their positions, must be good business men, and I cannot imagine a good business man following a policy of opposition and unfriendliness towards the contractors operating in his area. If he does such a thing, I think there is no doubt he would not occupy such a responsible position for any length of time.

I sincerely hope that a satisfactory agreement will be shortly arrived at. It is unthinkable that supply undertakings can do without electrical contractors.

#### Electric Vehicle Committee.

Considerable progress has been made during the past few months in developing the adoption of the electric battery vehicle in this country. I wish to impress upon members of the Association that it is impossible for the manufacturers themselves to give extended trials in more than a few towns. It is only by bringing and keeping these vehicles before the public that interest will be aroused in them, and for this purpose I consider that supply undertakings should be prepared themselves to bear some of the cost. Demonstration vehicles can quite well be used by municipalities for many of the operations that have to be carried out by them, such as street cleansing, collection of house refuse, conveyance of stores and materials between departments, &c. Money spent in pioneering work of this kind will, I am convinced, amply repay the supply undertaking. It also enables first-hand figures as to cost of operation to be given to prospective users. There is no doubt that in a large city many thousands of pounds of revenue will be obtained annually from the use of these vehicles when their adoption becomes general.

I would here like to remind you that, up to the present, the expenses incurred by the Electric Vehicle Committee have been met out of the funds of our Association. They estimate that during the coming twelve months their requirements in this respect will amount to about £200, and, with a view to meeting this expenditure, they are approaching the various municipal electric supply undertakings with a request that they should each contribute from one to three guineas towards this fund. They have also approached the manufacturing firms and others interested commercially in the movement, and I am glad to say have been met by a very liberal response.

#### The Industrial Committee of the Institution of Electrical Engineers.†

As a member of the now defunct Industrial Committee, I should like to explain to you exactly what was in their minds when they framed the resolution, which resulted in the dissolution of the Committee by the Council of the Institution. They recognised that in all industrial concerns, differences of opinion must arise on matters of policy and detail, and the same thing applies to the operations of the various existing associations, which are bound to come into conflict with each other at times. Such points of disagreement are usually settled by meetings and discussions between the associations concerned. Occasionally, however (and I venture to suggest that the present disagreement between us and the Electrical Contractors' Association over the wiring clauses is a case in point), disagreements arise which it appears almost impossible to settle. The Industrial Committee felt that a case of this kind was one in which they should be in a position to assist, and, if necessary, offer to arbitrate, and, in view of their not being able to do this under their constitution, they felt that some body should be called into existence which would be capable of offering its services in such an eventuality.

I am of the opinion that all the associations connected with the electrical industry (and there are many of them) should form from their members a central association, which could arrange conferences to consider disagreements between individual associations, and, if necessary, arbitrate upon the same, and which could be called together by any individual association requiring support in its operations, whether political or industrial. It rests with the various associations themselves to form such a body. It is obvious, I think, that the many and varied interests represented on the Council of the Institution of Electrical Engineers, which interests are largely individual and not really representative of the various associations, render it impossible for the Council to deal with disagreements between individual associations in the way that a body such as I have outlined could.

\* Slightly abridged.

### Combined Control of Municipal Gas and Electric Supply Undertakings.

I do not know whether the members of this Association read the very interesting address given by Mr. J. J. Newbigging, President of the Manchester District Institution of Gas Engineers, last month. The address was very fully reported in the issue of the *Gas World* dated March 7th, 1914. Towards the end of the address, Mr. Newbigging touches upon competition with electricity, and, coming as they do from the chief gas engineer to the Manchester Corporation, his remarks provide ample evidence that gas undertakings are beginning to fear the competition of electricity.

Mr. Newbigging did not refer to the real reason why electricity has been coming to the front so much faster than gas. This is undoubtedly due to the great reduction that has been made in the average price at which electricity is now sold to the consumer as compared with gas. A comparison of the Birmingham figures will be interesting: In the year 1901 the average net price of gas in Birmingham was 26·68d. per thousand cubic feet. In the year 1914 this has dropped to 19·41d. per thousand cubic feet, which is equivalent to a reduction to the consumer of 27·3 per cent. in the average price at which he is charged. In 1901 the average price received for electricity per unit was 4·37d. In 1914 this has dropped to 1·15d., a reduction of 73·6 per cent. in the price charged to the consumer. [Applause.] Here we have the real reason why gas is beginning to feel competition with electricity.

Mr. Newbigging makes some interesting suggestions by which gas undertakings could improve their position. He suggests supplying gas engines on hire purchase terms; this, I believe, has already been tried by some undertakings, and in this city at least it was discontinued. He also emphasises the point that the gas distributed should be absolutely regular in composition and be maintained at a constant and minimum pressure available to every consumer. The composition of gas distributed is, I believe, generally maintained satisfactorily, but the pressure at which it is supplied to consumers undoubtedly varies between very large limits in the outlying parts of a city, where it is used for lighting and where a constant pressure is most important. If competition with electricity will have the effect of making gas engineers recognise their responsibility in this direction, I am sure that even gas consumers will bless the introduction of electricity.

Another suggestion that Mr. Newbigging makes is that a competent staff of highly trained fitters should be established to clean consumers' burners free of charge and supply mantle renewals at cost price. An organisation of this kind, to deal with many thousands of consumers, must mean a very heavy expense. The idea suggested to the lay mind is that gas burners must be very unsatisfactory pieces of apparatus if they require frequent attention by highly trained fitters to keep them in proper order. Here, again, the gas consumers ought to be obliged to the competition of electricity for compelling the gas undertakings to look after their interests better.

Mr. Newbigging then goes on to suggest a combined control for municipal gas and electricity undertakings. I was under the impression that, when the question of combined control was raised early in 1911 between the gas and electricity committees of the Manchester Corporation, it was decided that the two committees should remain separate. The same question was discussed in Birmingham about the same time with a like result. I am of the opinion that the single control of gas and electricity undertakings would mean the total suppression of competition. [Cheers.] Instead of tending to foster keen rivalry between the two departments, it would effectually destroy that desire amongst the staff to improve upon previous records that is such an immense factor in the success of these public supply undertakings. To stifle this would be to deprive the ratepayer of the only real guarantee that he has for the most economical administration of both departments. Mr. Newbigging's charge that prices for current were sometimes cut down to an unjustifiable figure to secure business cannot be substantiated.

The sale of gas is largely controlled by the amount the undertaking can obtain for its by-products. This amount is frequently greater than the gross profits earned during the year. The electricity department has no by-products to sell except the useful employment during the hours of small demand of the generating plant and underground distributing mains, which have been purchased to supply the maximum load demanded during the winter months, and low quotations for current of high load factor are perfectly justifiable under these conditions. They are not given with the sole object of securing business, but to reduce the average cost of giving the supply, to the benefit of the whole of the consumers. [Applause.]

I maintain that it would be impossible for one manager and one Committee to work both departments in the interests of both classes of consumers. A man must become biased to a certain extent in favour of one or other of the branches of the supply, and it would be practically impossible for him to give an unbiased recommendation to his Committee on a point involving, for instance, whether the development of some new

area should be carried out by gas or electricity. Consumers would resent being told that they could only have one or the other, and such a policy would undoubtedly have the effect of driving manufacturers and others away from the city, whilst it is more than likely that the Board of Trade would be inclined to admit outside competition from power companies if they found that the statutory obligations for giving a supply were not being properly carried out.

There is no evidence whatever that the existing methods of single control of both gas and electricity undertakings have been unsuccessful. There is a field for both of them, as is shown by the increased outputs of both that are recorded year by year, and until such evidence is available, single control should not be considered.

### Centralisation of Electric Supply Undertakings.

Signs have not been wanting for some years past that the question of bringing isolated electric supply undertakings under one central system of supply has been occupying the attention of electrical engineers. Especially has this been the case in London, where attempts have been made to amalgamate the various companies by the formation of a central supply company. More recently the London County Council has been making very exhaustive inquiries into the same subject, and there is reason to believe is strongly in favour of centralisation of all the supplies, whether company or municipal. In the provinces, too, the larger municipalities have been extending their boundaries, and incidentally taking over the electric supply undertakings belonging to the areas incorporated, with distinctly beneficial results to themselves and to the areas taken over. Parliament has also recognised the principle by agreeing to the formation of the various power supply companies which are operating in several counties.

All these instances are steps in the right direction, though we are as yet a long way off the goal—where it will be possible to obtain, all over the country and at one rock-bottom price, a supply of electrical energy for any purpose, such as power, heating, lighting (and this will ultimately be such a small percentage of the whole that the poor load factor can be safely ignored), domestic requirements, traction by rail, road, or tramway, &c.

We are a nation of manufacturers, and to a large extent every inhabitant of this island is dependent upon our maintaining our position in the markets of the world. Our manufacturing factories can only hold their own in these markets if they can produce as cheaply as possible, and one most important consideration towards this end is the provision of cheap power and cheap transit for both goods and workmen. Other countries are recognising this; America and Germany, our two greatest trade rivals, are establishing centrally controlled systems of supply, which cannot fail to have a far-reaching effect upon their commercial welfare. We must do the same unless we are content to take a back seat in the future.

The larger municipalities in this country, such as Glasgow, Manchester, Birmingham, Liverpool, Leeds, &c., have pointed the way—now it remains for Parliament to tackle the question of nationalisation; whether by means of a Government Department or a Public Board of Management, such as the Port of London Authority, or a private company, subject to limitations as to dividends and prices to be charged for current supplied, is yet to be seen.

Until some such scheme is brought into operation, it is useless to expect any marked reduction in the cost of producing and distributing electrical energy below that obtaining in the large power stations now operating in this country. It is only by tackling the problem boldly, by being prepared to supply current at prices much lower than are ruling at present, and recognising that for a few years there must necessarily be a deficit on the large initial expenditure incurred, that it will be possible to attract and develop the large volume of business that will be necessary to make such a scheme a financial success in the future. It will be as necessary to face expenditure in pioneering work for this scheme as it was in the early days of electric lighting, with this difference, however, that the returns to be expected should come very much sooner. If such a policy is ever decided upon, it must be strictly adhered to, and it should incorporate the following outlines.

Large bulk supply power stations should be installed in various parts of the country having regard to the three following chief requirements: (1) Proximity of an ample quantity of coal. (2) Proximity of an unlimited supply of water for condensing purposes. (3) Proximity of the various large centres of industry where the major portion of the energy is likely to be required.

# I. M. E. A.

## ONE OF THE WORKS THAT HAVE MADE BIRMINGHAM FAMOUS.

### THE SIGNIFICANCE OF A NAME.

In the Electrical World the name "Tucker" has a significance all its own. It signifies everything that is good in design, quality, and finish. Engineers everywhere appreciate the fact that when they

### SPECIFY "TUCKER" SWITCHES

they get an article upon the quality and reliability of which they can absolutely depend, and in addition puts upon their work that little touch of "perfect detail."

**J. H. TUCKER & CO.**  
KING'S ROAD, HAY MILLS,  
**BIRMINGHAM**

#### LONDON:

217, Shaftesbury Avenue, W.C.  
TELEPHONE - - 3215 GERRARD.  
TELEGRAMS - "TUCKERANCY."  
WEST CENT.

#### GLASGOW:

221, St. Vincent Street.  
TELEPHONE - - - 5045 CENT.  
TELEGRAMS - - "SWITCHES."

TELEPHONE - - - 101 ACOCK'S GREEN  
TELEGRAMS - - - "SWITCHES"

Railways, of course, cover practically the whole of the country, so that these can be fed economically at any point or points throughout their length.

As soon as these bulk supply stations are available and the distributing trunk cables installed, the majority of the small generating stations in the country should be at once shut down and utilised as sub-stations. It would probably be found most satisfactory in many cases to adhere to the existing methods of distribution, and to utilise these as far as they will serve, possibly, as they become filled up, installing alongside of them other schemes for distribution of energy which may prove more economical to handle.

And now a word about the engineers who are at present in charge of these isolated supply stations. It will probably be concluded that when all these stations are shut down the engineers in charge of them will not be required, and it is only human nature to resist the formation of such a scheme from the fear of being thrown out of employment. I consider that it would be the worst possible form of so-called economy to dispense with the services of a single man that is at present employed in all these undertakings. The very object of the scheme is to increase enormously the business to be handled in all these centres by giving the supply at a much more attractive price. The men on the spot have the best knowledge obtainable for pushing the business and developing the distribution of the bulk supply that they would receive, and the chief engineers in charge would be especially valuable in this direction. We electrical engineers have to be managers of our businesses as well as engineers in charge, and the business control is every bit as important as is the engineering control. The commercial side of the business is so dependent upon technical matters that it is necessary to have an engineer at the head. I do not see, therefore, that there need be any apprehension in the minds of the existing engineers in charge that they will not be required if such a scheme comes into being.

The main distribution should be carried out wherever possible by means of overhead trunk mains, and provision should be made for reasonable wayleaves to be compulsorily granted. Without special powers regulating the granting of wayleaves, it is probable that the cost of obtaining them would very nearly kill the saving of overhead trunk lines compared with underground cables. Another great advantage of the scheme would be that the cast-iron boundaries of existing municipalities and companies, which at present limit the various areas of supply, would entirely disappear.

London is now considering working out its own salvation on lines such as I have suggested, and it will be a great pity if the scheme that is finally adopted is not so laid out that it will be possible to work it in as part of a large national scheme such as I have indicated.

It is pretty evident that Parliament has its hands so full that there is not much hope, for the present at all events, of any move being made in this direction. I suggest, however, as this scheme is so vitally important to all industrial centres, that in their own interests the large municipalities, who at present control the major portion of the bulk supplies in the provinces, should meet together and discuss the matter, and, if possible, formulate a satisfactory scheme which could then be brought jointly before Parliament, to be subsequently developed on proper commercial lines.

In my opinion, this method of procedure is the most suitable one to adopt, and the justification for it is:

The supply of electrical energy for all purposes, whether industrial, domestic, or public utility, at a price far below what is now being paid:

- (a) For the benefit of the community as a whole.
- (b) For enabling our manufacturers to compete successfully with their rivals abroad, who, it must be remembered, are developing their resources on these very lines.
- (c) For the abolition of smoke in our large cities, and the consequent general improvement in the health of the community.
- (d) For the conservation of our coal supplies, which will be utilised on the most economical lines at present known to science, and

(e) For the upholding of our position as the leading country in the world of commerce, which position is being assailed more and more every year.

These reasons should surely be sufficient to make the controllers of our large industrial communities look carefully into the question of centralisation of the supply of electrical energy. [Prolonged applause.]

Previous to the reading of the Address a welcome was given to the members and visitors by the Lord Mayor of Birmingham, and after Mr. Chattock had sat down a very cordial vote of thanks was given him by acclamation on the motion of Alderman Bruce (Sunderland), seconded by Mr. H. Richardson (Dundee).

## NOTES ON THE COMMERCIAL DEVELOPMENT OF ELECTRICITY SUPPLY IN MODERATE-SIZED TOWNS

By W. A. VIGNOLES (*Chief Electrical Engineer, Grimsby*).

THIS Paper was taken after the reading of the Presidential Address. In it the author discussed problems to be met with in the supply of electricity in towns of about 100,000 inhabitants, based on his own experience in his own town, Grimsby, which has a population of about 77,000. Factories there are few in number, though there are the usual miscellaneous workshops incidental to a shipping town, and a few large sawmills. The latter, however, usually employ steam for power raising, burning their wood refuse instead of coal.

### Business-Getting.

Grimsby has no special powers for selling apparatus to consumers, and in such cases the author thinks that the establishment of a showroom is not worth while, as equivalent results can be obtained in other ways at less expense. For instance, the engineer in a town of about 100,000 inhabitants had stated recently that his showroom cost him £600 per annum, excluding canvassing staff; in Grimsby excellent results have been obtained by advertising with considerably less expenditure. In 1912-13, £268 was spent, and in 1913-14 £250. The increase in private consumers during the last year was 315, representing 17,714 lamps; motors increased by 316 h.p., the revenue from supply to private consumers by £2,144, and the heating and cooking connections by an equivalent of 3,411 8-c.p. lamps. The author then reviewed briefly the methods of advertising employed, and mentioned that the cost of £250 represented a very small proportion of the turnover, which was between £20,000 and £24,000. He referred to the activities of the British Commercial Gas Association, which is spending thousands of pounds on its publicity campaign, and suggested that the electric supply industry should combine to place the merits of electricity supply before the country in a forcible manner, as the Electric Supply Publicity Committee had not done much more outside London than supply leaflets and advertising literature. He suggested that the I.M.E.A. should appoint a Committee with full powers to confer with the Electricity Supply Publicity Committee or any other body, to endeavour to formulate some scheme by which a co-operative system of publicity could be put on foot for the benefit of electricity supply generally. Local authorities whose accounts are subject to Local Government Board audit, were hampered by a recent ruling that advertising literature may be purchased, but that authorities have no power to subscribe to the funds of an association organised on the lines of the Commercial Gas Association. A different constitution, he suggested, might get over the difficulty; if not, the sooner the I.M.E.A. Electricity Bill, in which there is a clause dealing with this question, was passed, the better. A further difficulty in the way of a large combined municipal scheme of advertising was that in a number of towns both electricity and gas are in the hands of the Corporation, but, he said, there did not appear to be any gas undertaking in the country that had seriously suffered from the competition of even the most energetic electricity supply authority.

Exhibitions and demonstrations were useful, especially when any new development came along; but the cost was heavy, and they should not be held too frequently.

Every undertaking of the size under consideration, Mr. Vignoles continued, should employ an engineer as canvasser or representative, devoting the whole of his time to this work. He should send through a daily list of his calls, and should report personally in any cases where he has difficulty in securing the business; in these cases the manager should visit the possible consumer, even if the installation in question is only a small one. Arrangements should be made with the borough surveyor to supply the department with the names of persons who have submitted building plans for approval, and to give particulars of any new roads or estates that are being laid out, and strenuous efforts should be made to induce the speculative and other builders to wire new houses.

The relations with wiring contractors was next discussed, and the author seemed to think that one of the difficulties was that the contractor often lost time and possible consumers by endeavouring to force his views on them, instead of giving the consumers what they wanted. In Grimsby also great trouble has also been experienced at times in getting contractors to follow up inquiries that have been obtained. To get over these difficulties the Department offers free advice

to all consumers, and for a small fee, 2½ per cent. on the value of the work with a minimum of 5s., undertakes the preparation of a specification, and superintends the carrying out of the work. Alternatively, any consumer can obtain free of charge an outline scheme for the lighting of his premises. The result has been a marked improvement in the methods of illumination in recent installations, and consumers are better satisfied. In the same way schemes are prepared for power users. A systematic method of dealing with complaints was also detailed.

When new devices or apparatus are placed on the market, the Department purchases a few examples and lets consumers have them on loan for trial. The consumers' engineer usually deals with these matters, and when the apparatus is on circuit looks after it until satisfaction is obtained, and endeavours finally to effect a sale through a contractor.

At Grimsby there is a friendly arrangement with the local contractors by which the Department hires out motors and starting apparatus, arc lamps, cookers and heaters, and provides installations and apparatus on hire purchase. All wiring work is done through a contractor, and no apparatus is hired out that is of less value than £3 10s. In many cases the Department takes over the hire purchase of apparatus or installations provided and arranged for by contractors, in which cases the profit is shared. On the other hand, although in the early stages of the development of the power load four-fifths of the motors were on hire, now by far the larger number of motors are purchased outright from contractors. One of the principal reasons for the rapid development at Norwich is that installations are provided if required on a rental basis, and undoubtedly all towns should be in a position to give this facility. But this can be given equally well by placing the actual work in the hands of a contractor, the Corporation merely doing the financing. It is advisable to combine the charge for the hire of the wiring with the fixed charge of the rateable value system, so that the consumer pays a fixed sum per annum, which includes the cost of the wiring of his premises and the capital charges for electricity supply, and the only additional payment he has to meet is the cost of current at the running rate of 1d., or ½d., per unit. No manager, said Mr. Vignoles in concluding this portion of his Paper, need sit down with folded hands and say, "I cannot adopt progressive methods to develop the business, because I have no powers to institute a sales department."

Dealing with the mains question, Mr. Vignoles advised undertakings not to exercise their right too freely of exacting a guarantee from new consumers outside the compulsory area to consume electricity to the value of 20 per cent. on the capital outlay involved in laying any new mains required. In new streets guarantees should certainly not be asked for, but mains laid as a matter of course before the houses are built; and broadly the principle might be stated to be that a guarantee should not be asked for unless there is a strong probability of the undertaking losing money by giving the supply, and it is felt that it would be better to be without the consumer. This question had been forcibly brought home to the writer by the fact that in the past a number of consumers had been lost by asking them for guarantees, and a few years afterwards mains had actually had to be laid down past the premises where supply had been wanted. In Grimsby a very large length of 7/16 three-core distributor has been laid and has given excellent results in providing for extensions in streets where there are numbers of small houses. The writer's present practice is to run one cable of this size in the first instance, and if additional consumers are obtained, to lay a 19/16 cable on the other side of the road.

The half-watt lamp then came in for mention. The present prosperous condition of electrical undertakings, said the author, is entirely founded, as far as the lighting branch is concerned, on the metal filament lamp. The only way in which the half-watt lamp could hurt undertakings would be if it was introduced in such sizes and at so low a price that it could be generally used for the smallest houses. If this came to pass, the question which is already agitating managers, as to how to ensure sufficient revenue from small houses to pay the capital charges on the cost of the service, in addition to the cost of current, would become more acute. Meantime, however, any decrease in units sold will be accompanied by a corresponding reduction in the maximum demand, and any loss of revenue will be made up by new business.

In Grimsby about 660 metal filament lamps are now in use for street lighting, and there is a very substantial margin of profit after providing for all capital charges on the mains, posts, lamps, &c., at the rate of 12 per cent. per annum, and charging the electricity used at 1d. per unit. All capital

expenditure for this purpose is provided out of revenue, so that the interest on the money is saved.

Returning to the small consumer problem, the author stated that in Grimsby supply is being given to consumers at present whose annual bill only just reaches 80s., while with slot meters many consumers are paying less than this. By standardisation and by adopting a system of looping services, running one cable for each pair of houses, the average cost per service has been steadily reduced from £3 19s. 10d. in 1906-7 to £2 17s. in 1912-13. With the smallest consumers and in premises where the tenant is likely to change frequently, it is very desirable to use slot meters; the revenue that has been obtained in Grimsby from these in the last few years has been as follows:—1911-12, £201; 1912-13, £270; 1913-14, £383. In order to keep in touch with the consumer the meters have been arranged for 5d. per unit, but when the meter is cleared 2d. in every 1s. is returned, so that the nett cost is about 4d. per unit instead of 3½d., the usual flat rate. Meter rents are not charged, so a small consumer pays no more on this system than he would on the ordinary rate. The system of refunding a proportion of the money put in is popular, as the meter in a way acts as a savings bank, and, in fact, it is strongly suspected that the "man" has to provide the 1s. while the lady of the house draws the rebate when the collector comes round.

Heating and cooking were referred to briefly in the Paper. In Grimsby with a 1d. rate, and without any appreciable number of heaters being let on hire, the sales for heating and cooking amounted to £324 last year. It is anticipated that with the proposed rateable value system, at 15 per cent. and ½d., a very large development will take place, especially as the various types of "heaters," notably the class using red-hot elements, are being rapidly improved. It is hoped to induce consumers to purchase their own apparatus, if not outright, at least on a short hire-purchase basis. With cooking the complaint is still that the apparatus is too expensive for the small householder to buy, while it is difficult to get consumers to pay 15s. per quarter for cooking apparatus when they can hire a gas cooker for 8s. 6d. Approval was given of Mr. Seabrook's experiment to charge 8s. 6d. per quarter rent, and to add ½d. per unit to the price of electricity used through cookers on hire, this ½d. being credited to the hire account. In order that the manufacturers may cheapen price by standardisation and greater output, Mr. Vignoles suggested that a number of undertakings should combine in adopting a particular make of cooker. While hesitating to recommend that the I.M.E.A. should appoint another Committee on this question, his own opinion is that the Association should have a number of permanent Sub-Committees, each dealing with and fostering the development of some particular branch of electricity supply.

To give the cooking business a start the author regards it as essential that one or more of the staff should actually use the cookers and study the art of cooking in a general way. A lady should afterwards be appointed to take special charge of this Department, and to advise consumers on the use of the apparatus.

### Financial Control.

Mr. Vignoles then put forward the view that the whole control of the undertaking, business-getting, engineering, and finance, should be under one supreme head; that the department should be entirely self-contained, the books kept, accounts collected, and balance sheet prepared by a staff supervised by an accountant under the control of the manager. He does not agree with a large part of this work being done in the Borough Treasurer's Department; many difficulties occur, because the clerical staff is not in close touch with the facts and details of the working of the undertaking. He has been informed by many managers that they have great difficulty in getting figures and statistics at the time, and in the form, in which they want them, and in one case it was actually proposed to get over the difficulty by keeping duplicates of a number of the books. Where the Borough Treasurer controls the finances, Mr. Vignoles contends, he naturally exercises a considerable influence in the financial management, and is frequently more interested in devising means for keeping down the rates than in seeing that the financial position of the undertaking is unassailable.

As an example of the mistake of contributing profits to the rates, the Author cited one instance in which the Council in one year voted the whole of the profits for the following year, estimated at £9,000, to the rates, notwithstanding the fact that they had a whole engine-room full of obsolete plant. The surplus only amounted to £7,000; not to be beaten, the Council in the next year voted £6,000 to the rates, to find that the surplus was £4,000 only. He believes in devoting the larger portion, if not all the profits (after paying back to the rates any sums taken for the undertaking) to the strengthening of reserves, and to the reduction of the price of electricity to as

low a figure as possible, and he approves of Mr. Pearce's suggestion that a limit should be placed by Parliament on the contributions to be made to the rates. This policy, while being the soundest from the point of view of the financial stability of the undertaking, would, in practically all cases, be the best for the district. A cheap supply of electricity brings prosperity to many towns by encouraging the use of machinery and causing new industries to be established.

The Paper next dealt with the raising and repayment of capital. When capital is raised by the issue of stock, the Author is in favour of investing the sinking fund in the undertaking, using the money to purchase new machinery instead of raising further capital. It is, he says, open to any Corporation to do this, under the Local Government Board Stock Regulations of 1901 and 1902, amending those of 1891 and 1897. All these regulations are issued under the provisions of the Public Health Act of 1890. He mentions, however, that the simplest method of raising money for electricity supply purposes is by the borrowing from companies, societies, or individuals, on the security of the district rate, and to repay the loan by way of annuity—an equated payment of principal and interest, calculated so that while the interest is large the repayment is small, making the burden on each year's working equal.

The Grimsby Corporation have never taken up a loan for their electricity undertaking for any period of less than fifteen years. The Local Government Board has approved the borrowing of money for certain purposes with the term of repayment fixed at five and ten years, but in these cases the money has been taken out of the profits of the undertaking. This has saved expenses in negotiating the loan and interest. In this way the undertaking provides for all new meters, public lamps, and posts, while it also provides in the same way for small extensions of mains and for the wages paid to men in permanent employ when working on capital account.

On the question of temporary loans, the Author referred to a note in the Press some time back stating that the St. Marylebone undertaking were borrowing £10,000 from the St. Marylebone Borough General Fund account at 2½ per cent. interest, this being the rate which the General Fund would have received from the bank.

As to the provision for depreciation, Mr. Vignoles stated the following principle:—Depreciation must be provided so that the value of the assets at any time at least equals the capital outstanding, i.e., the total capital raised, less the amounts repaid, or providing for repayment, and less the depreciation, reserve, and sinking funds. To value assets the original cost must be written down on the basis of the estimated number of years of life, and in addition an allowance must be made for possible obsolescence by the introduction of new and more efficient apparatus before the expiration of that period.

The following are the loan periods sanctioned by the Local Government Board in recent cases:—Land, 50 years; foundations, 30 years; buildings, 30 years; Water-tube boilers, 15 years; generators, 18 years; conveyors, 15 years; engines and other machinery, 18 years; turbines, 18 years; cables (solid, in wood trough), 25 years; cables (ducts), 25 years; services (either armoured or laid solid), 15 years; rotary converters and motor generators, 15 years; accumulators, 10 years; arc and incandescent lamps and posts, 10 years; meters, 5 years; switchgear instruments, 18 years; water recorders, 15 years; cooling towers, 10 years.

A reserve fund acts as a protection to the capital account, but it must be borne in mind that it may be called upon at any time to provide for a deficit in the revenue account, any amount so transferred ceases to be available for depreciation, as it has passed out of the capital account. In providing depreciation, therefore, a margin should be allowed, over and above the calculated amount required, to provide for such a contingency.

With these short periods the author thinks that there is every probability that nothing further is required in the way of depreciation, and that the machinery will, in most cases, be in efficient use after the whole of the loan has been repaid. Most undertakings, however, have obsolescent machinery in use on which loans are still outstanding, and in one case a large number of engines were out of date before business had developed sufficiently to provide load for all the sets. In the Grimsby accounts there is no depreciation fund so-called, but this is represented by the repayments of loans, the revenue contributions to capital outlay, the reserve fund, and the sinking fund.

Mr. Vignoles thinks it probable that the Local Government Board would give permission to the borrowing of the whole amount required for new plant to replace obsolete, if sufficient depreciation had been provided and ear-marked in the accounts to meet the whole amount outstanding on the plant to be scrapped, even if such depreciation had already been invested in the undertaking in the form of new assets.

In Grimsby the difficulty of having working capital is got over by not investing the reserve fund, but leaving it in the ordinary banking account. The Local Government Board recently reminded the Corporation that, under the Electric Lighting Acts, this money should be invested, but it was pointed out in reply that if this were done the only alternative would be to borrow money from the bank, and that the Corporation

had no powers to do this; also, that the course which they had adopted was more economical, as the reserve fund if invested would only have earned about 3½ per cent., whereas the bank would have charged 5 per cent. for the overdraft. The necessity for working capital was also pointed out to them, and the Board have not raised any further objections.

The following table given in the Paper is interesting:—

Year ending	Grimsby.		Ipswich.		Norwich.		Southampton.	
	1907	1911	1908	1911	1907	1911	1908	1911
No. of Consumers per mile of distributor	31.5	44.4	31	52.2	101	92	50*	59*
Total Revenue per mile	£ 568	£ 550	£ 744	£ 930	£ 808	£ 793	£ 1,513*	£ 1,061*
Revenue per Consumer	£ 18.1	£ 9.0	£ 24.2	£ 15.3	£ 8.15	£ 8.5	£ 30.4	£ 18.1
Revenue per £ Capital spent on Mains and Services (exclusive Public Lighting)	0.611	0.83	0.120	0.127	0.710	0.85	0.92	0.98
Average Cost per Service	3.19.10	2.17.0	4.2.1	3.8.5	4.0.0	3.5.0	3.4.3	3.19.5

\* Per route mile in the case of Southampton.

### Cost of Supply.

Many progressive managers advocate the principle of selling electricity not on the basis of cost but on what it will fetch in the market; but the Author is of opinion that this should not be done if it involves selling below what it costs unless:—(1) It can be shown that selling at the proposed price will so reduce costs that ultimately a profit will be made; or (2) that by selling at a loss other business, which would not otherwise be done, can be obtained upon which the losses can be made up. This is not a suggestion that the "Point Fives" are selling at too low a price; if electricity is being sold at a loss, the Author says, it will probably be to the short-hour consumers who are paying on a flat rate, such as banks, offices closing at five, and early closing shops. At a flat rate of 3½d., the price in Grimsby, he says, they almost certainly cause a loss to the undertaking at the present time.

Mr. Vignoles has worked out that the average cost of generation, as long as the conditions remain the same, follows a definite law, which is similar in form to the Willans law for the steam consumption of an engine. The total cost of generation per annum (not the cost per unit) is equal to a fixed sum, plus a small running cost per unit sold. This is illustrated in

FIG. 1.—GRIMSBY GENERATING COSTS.

Fig. 1, which shows for Grimsby the amounts spent on generation during the years 1905 to 1911.

Fig. 2 shows coal, oil, and wages plotted for four towns. A straight line (see Fig. 1), is drawn fairly easily through the points plotted for coal, oil, and wages, the coal cost having been adjusted to a uniform price of 7s. 5d. per ton for ½-inch slack, this being the highest price during the period. The equation for this straight line is that the standing charges are £1,750, while the running cost, i.e., the extra cost for oil, wages, and coal, is 0.313d. per unit. In spite of the varying cost of repairs each year, the upper line lies fairly among the points; the formula for this is £2,450 plus 0.341d. per unit. The cost of generating the supply required by any consumer will be 0.341d. plus a proportion of the standing charges of £2,450, based on his maximum demand. In certain cases, where new classes of business are being considered, the Author thinks it may be advisable to ignore the standing charges, as these are being met by the revenue received from existing supplies. This is the attitude adopted by the "Point Fives," and it is a reasonable one provided that their charge covers the extra or running cost of supplying the extra units, any extra capital charges involved, and leaves a margin of profit for the benefit of the undertaking.

The division of the generating expenses into standing charges and running costs was advocated by the "Joint Committee of the I.M.E.A. and M.T.A. on charges for electrical energy for traction purposes from combined stations," and they gave a method of calculation. Applying their method to the Grimsby accounts for the year 1912-13, two years later than the last point marked on the curve in Fig. 1, gives the division as:—Standing costs, £2,394; and running costs, 0.36d., figures sufficiently near to those proved to be correct by the straight line in diagram Fig. 1.

The management expenses can be divided into two principal items: running the undertaking, and development work in seeking and providing for new business. In the case of the Grimsby undertaking, fully one-third of the management should

be debited to the latter as it includes the engineering charges for all new extensions, with the exception of any special draughtsman's work. In allocating the management costs, the expense due to the running should be debited to the various classes of supply in proportion to the maximum demands, while it is suggested that the development expenses should be allocated in proportion to the profit made. That is, that it should be taken out of profits, and not shown as an expense against any particular class of supply.

The capital charges must also be allotted according to the maximum demand on the plant.

Working out an example of the cost of bulk supply or that for cooking at Grimsby on this basis, the author made the net extra cost under present conditions, with coal at the highest price it has reached in the last five years, to be £2 11s. per kw. of

FIG. 2.

increase in the peak on the basis of new plant, or £3 18s. if the average cost of the present plant be included, with an extra of 0.34d. to 0.36d. per unit sold.

At Southampton, in 1913, the load factor including all units sold was 22.23, and excluding units sold for cooking 19.35, which points to the effect of the cooking load on the peak being small.

From the figures given, Mr. Vignoles concludes that electricity can be sold for cooking under the conditions at Grimsby on a rateable value system of 15 per cent. and ½d. at a substantial profit.

A note at the end of the Paper touched on the question of turbine generating sets of 1,000 kw. and upwards which are now becoming desirable to bring down the generation costs in towns of moderate size. With such units it will be necessary to use alternate-current generators or geared turbines, and in several cases the former have been installed in continuous-current stations, a rotary converter being also erected in the station to make the conversion. The Author suggests that it would be better then to take advantage of high pressure to reduce the capital cost of the feeders, and at the same time to arrange to supply a few large consumers with high-tension three-phase current giving a slight advantage in the price. The change from D.C. to three-phase, he thinks, is being forced by the changing conditions.

The Discussion on this Paper is reported on p. 347.

## DESIGN AND OPERATION OF MODERN BOILER-HOUSE PLANT

By S. E. FEDDEN (*Chief Electrical Engineer, Sheffield.*)

YESTERDAY the members proceeded to Coventry, and the meeting was devoted to Mr. Fedden's Paper with the above title.

Ample facilities for dealing with ashes, said Mr. Fedden, is becoming a very serious source of expense and concern in large cities, because of the difficulty of obtaining tips within a reasonable distance of the station. In Sheffield the cost of carting has increased no less than 40 per cent. within the last few years. This increased expense, he continued, can appreciably increase the cost per unit, and it may be necessary to take into consideration whether it is not worth while to buy a high-priced coal with, say, 4 or 5 per cent. of ash, instead of the cheaper class of engine slack with its 10 to 15 per cent. of ash.

The author has lately gone to considerable expenditure to deal with ashes. A lease of a valley adjacent to the power house has been obtained, and a steel bridge erected for guard purposes over the main line of the railway. A ropeway 200 yds. long has been installed, capable of dealing with 20 tons of ashes per hour. This method of dealing with the ashes was arrived at after investigating the undermentioned alternative schemes, which worked out as follows:—Railway, 2s. 9½d. per ton; cartage, 1s. 11d. per ton; ropeway, 1s. 3d. per ton. [The aerial ropeway is described in detail later in the Paper.]

Dealing next with the facilities for getting in coal, Mr.

Fedden considered it advantageous to choose a site having a high level siding, so that the trucks come in straight off the railway over the top of the bunkers, thereby doing away with the expense of installing and running coal conveyors. It costs much less to elevate the 5 per cent. to 10 per cent. of ashes than to handle the full quantity of coal, in addition to the probability of having to lift the ashes again. Neepsend power-house is arranged on this plan, and the problem looked rather a formidable one, as the author had to cut sheer down 60 ft. and excavate approximately 30,000 cub. yds. of material. Trial holes, however, had been taken before deciding to utilise the site, and it was found that the material was suitable for brick making. The author, therefore, bought a few thousand bricks and built three Newcastle case kilns, which were used for providing bricks for building a permanent kiln and chimney. A large portion of the material was found suitable, and was converted into bricks for the power-house, other portions of the excavations were found to be good hard rock, suitable for concrete and wall building, and the foundations were excellent. The expensive-looking site, therefore, turned out to be a cheap one as regards capital cost. The capital cost per kw. for the first section of the station is below £10, including the cost of land and sidings.

From the drawing on p. 344, which also shows the ground provided for tipping ashes, it will be seen that although the turbines are widely spaced, the boilers have to be cramped, in order to obtain the necessary amount of steam. The original plan of boilers in line with the engine-room had to be amended, and the boilers placed in a transept running out of the original boiler-house.

The present equipment of the boiler house consists of eleven water-tube boilers of the following capacities.

	Nos. 1 to 4.	Nos. 5 to 8.	Nos. 9 to 11.
Heating surface ...	6,210 sq. ft.	8,016 sq. ft.	9,611 sq. ft.
Grate area ...	80 sq. ft.	144 sq. ft.	192 sq. ft.
Normal evaporation of water per hour ...	50,000 lbs.	35,000 lbs.	48,000 lbs.
Steam drums ...	3 of 3' 6" diam.	3 of 4' 0" diam.	3 of 4' 0" diam.
Mud drums ...	2 of 3' 0" diam.	2 of 3' 0" diam.	2 of 3' 0" diam.
No. of Tubes ...	432	540	648
Stokers ...	Bennis.	Chain grate & Underfeed.	Chain grate.

Three more boilers are under construction for next winter's load.

The boiler house is provided with two pump rooms. No. 1 contains four feed pumps of the long stroke vertical compound double-acting type, three having a capacity of 3,000, and the fourth 10,000 gals. per hr.; also three live steam feed water heaters, capable of raising the temperature from 85° to 135° F.

No. 2 contains four feed pumps of a similar type, with a capacity of 10,000 gals. each per hr.; one rotary feed pump, motor driven, with a capacity of 20,000 gals. per hr.; one motor-driven centrifugal pump, with a capacity of 10,000 gals. per hr.; five live steam feed water heaters.

The duties of the last-mentioned pump are of a three-fold nature:—(1) In the event of the town water supply being cut off, water can be pumped from the river direct to the overhead feed tank. (2) It can be connected to the existing water service mains where the town supply is not available to provide a supply of water for fire purposes. (3) Economy is effected by using the river water in place of town water for cleaning out the boilers.

An overhead tank is fixed above each pump room; the capacities are 20,000 and 25,000 gals. respectively. The exhaust steam from each steam feed pump is led to the overhead feed water tank, the exhaust pipe having a silencer fitted. It is, however, essential that great care should be exercised to prevent oil getting into the economisers and boilers.

The whole of the steam piping is wrought steel lap welded, with cast steel tee pieces. The valves and bye-passes are also of cast steel suitable for use with superheated steam. The steam pipe is 10" and 12" diameter single main, and runs the whole length of the boiler house. The turbines and boilers are connected to the main steam pipe by single connections, and the steam of the feed pumps only having a ring main. The water mains are of cast iron 6" diameter with flanges bracketed.

There are two main feed pipes, hot and cold, running the whole length of the boiler house, and these mains are inter-connected by valves so that if a fracture occurs either main can be put into commission. Further, the pipes are arranged in standard lengths as far as possible, so that a fractured pipe can be readily replaced. Expansion pipes are provided by means of copper bends in both mains, and there are copper bends in each branch connection to the boilers and economisers. The steam and feed water mains are carried on roller supports when ever possible, and sling supports in other positions.

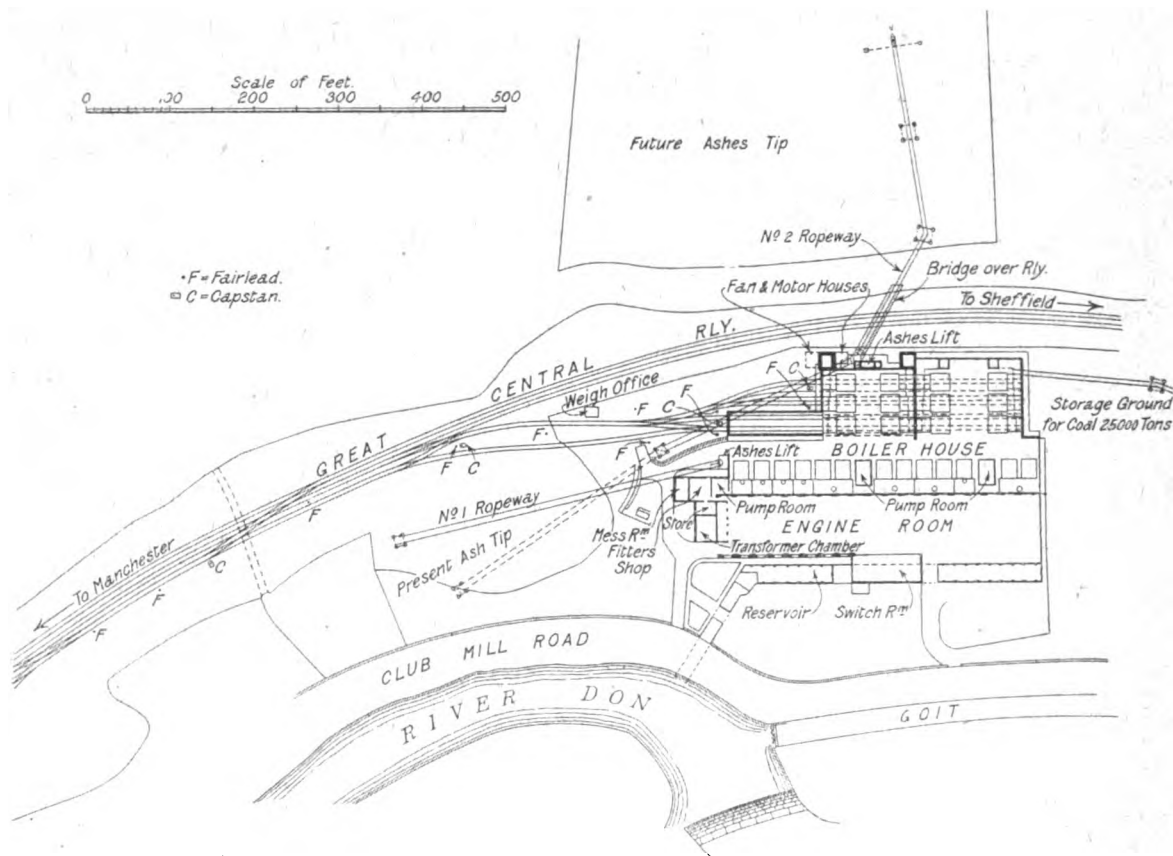

Provision is made for a three weeks supply of coal opposite each boiler on the siding level, and each boiler has a shoot

holding about 100 tons of coal, which feeds by gravity into the mechanical stoker hopper. At the top of these shoots, and, in fact, between all the railway lines over the bunkers, is provided a steel grid to prevent any large lumps getting through. Bottom-emptying trucks are brought directly over these shoots, and, with the exception of trimming from the extreme corners of the trucks, the major portion of the coal is never handled from the time of putting it in the trucks at the colliery until it is taken hold of by the mechanical stokers.

At the ends of the five railway lines over the top of the bunkers a traverser is provided for the transference of the railway trucks from one line to the other. It has a working capacity of eighteen tons gross, and is electrically driven by means of an 8 h.p. two-phase motor running at 700 r.p.m. on a 200-v. 50-period circuit.

The shoots are fitted with measuring chambers and indicating gear, and the coal is led through breeches pieces to the stoker hoppers. It is frequently claimed that measuring chambers are most inaccurate, but the author contends that this is not so. All the coal in stock is levelled off every month, and surveys by three men from different departments are taken independently. The difference between the stock as shown in the stock book

At Neepsend the ashes are elevated to an overhead hopper and taken away to the tip ground already mentioned by a bucket ropeway. This automatically tips the ashes wherever required, whilst the empty carriers proceed onward without stopping or being handled in any way, and are automatically conveyed around a return terminal back again to the loading terminal, where they are automatically disengaged from the hauling rope, and then stand ready for loading again. The loading rail is at a height of 17 ft. above ground level. The ashes are collected in the basement underneath the boilers in ordinary tipping wagons, running on a 2 ft. gauge tramway. The wagons are then run to an electric hoist just outside the boiler house, and raised 40 ft. above the basement level, where their contents are tipped into a hopper of 54 cu. ft. capacity. From this hopper the ashes fall through a shoot, controlled by a hand lever, into the boxes of the ropeway carriers standing on the loading rail. The automatic return terminal of the aerial ropeway is mounted on eight steel wheels running on a pair of rails, so that as the ground around is filled up in course of time by the tipping, the terminal itself can be moved along. In this way it will be seen that the whole installation can be moved round fanwise for a total length of 190 feet, so that in time the whole of the low ground to the

GENERAL PLAN OF NEEPSEND ELECTRICITY WORKS.

obtained by means of the measures and indicators and that obtained by the independent surveys is not very great: Stock, 6,527 tons; No. 1 Man, 6,426 tons; No. 2 Man, 6,461 tons; No. 3 Man, 6,582 tons.

The next important item in regard to a boiler house is the water supply. If good water is not available it should be treated at any reasonable cost before it goes into the economiser or boiler, and if it is very cold, say below 80° F., the temperature should be increased to 110° F., even though live steam feed water heaters are installed to effect this. The author will not admit that warming water by live steam is economical and saves coal, but he concedes that any loss incurred by heating the feed water by live steam is well and amply repaid in the saving of repairs to the economiser and boiler tubes.

The live steam feed water heaters which the author has had in use satisfactorily for some years have been those fitted with a patent indented tube. This is made by taking a plain round tube and indenting it in a regular manner at right angles, so that fluid passing through the tube is thoroughly broken up and diverted into contact with a large amount of impinging surface.

The ash disposal arrangements, in the author's opinion, should be such that the ashes can be lifted from two or three points in the ashes trench; and whether rails, trucks, elevator or suction plant be employed, it is well not to be absolutely dependent on any one of these, but openings should be left in the boiler-house floor covered with plates, so that the ashes can in an emergency be taken away by carts driven into the boiler house firing level or underneath if the lay-out will allow.

left of the ropeway will be automatically filled up. The whole installation, including the loading and despatch of the carriers, is worked by one man. An additional shoot has been connected to the hopper so that in the event of a breakdown of the ropeway a railway truck can be run under this shoot to give an alternative means of getting rid of the ashes.

A suction plant is about to be put in for all new boilers, and eventually for the old ones, by which the author expects to save considerable labour, and also to do away with much dirt and dust, besides causing the atmosphere in the ashes trench to be less vitiated by the fumes, and to clean soot from soot chambers and economisers, thus reducing the amount of manual labour. The system of suction plant has been fully described within the last year or two [see *ELECTRICAL ENGINEERING*, July 25th, 1912, Vol. VIII., p. 421], and the author feels that there is no need for a further description. However, manufacturers' opinions seem to differ very considerably as to the means of conveying the ashes and gritty matter by pipes to the receiving chamber. Some recommend a blower of the Roots type, while others recommend a continuous suction by means of a motor-driven fan. A similar difference of opinion appears to exist as to the advisability of introducing a screening plant into the suction circuit so as to exclude the fine particles of dust from the veins or slides, which would be quickly scored away.

As to the type of boiler to be used, Mr. Fedden expressed

the view that circumstances force careful engineers to use practically one of five or six types in this country, and "of course these are of the water-tube type, Lancashire or marine boilers being totally unsuitable for obtaining the large amount of steam required on the small area available in a modern power-station." There is very little to choose between these five or six types, continued Mr. Fedden; they all want good water, one claims a little better efficiency, the other claims less maintenance. He thinks that from experience the boilers made in this country are of first-class design and workmanship, and with due care the cost of maintenance should not be heavy. He is in favour of the vertical tube boiler, having experienced very good results from this type, but other engineers have no doubt obtained equally good results from the horizontal tubed boilers. To get the maximum evaporation out of the smallest floor space means a large grate area and the burning of as much coal as possible per sq. ft. There is, of course, an economic limit to this high rate of combustion, both as regards efficiency and maintenance, but it is very comforting to feel that boilers can be pushed to 40 or 50 per cent. above their normal working load in case of emergency. In the event of a very high rate of combustion becoming general and proving itself satisfactory, there will have to be a re-designing of the boiler combination by the adoption of larger economisers, superheaters, flues, feed-pipes, steam-pipes, fans, coal bunkers, and ash-disposal arrangements.

If land is scarce, an economiser raised above the outlet damper of the boiler has much to recommend it, as, of course, there is then no check to the natural flow of the gases. As an offset to this, however, additional expenditure is incurred in steelwork to support the economiser, and also in the building of a high boiler-house, and it may cause a considerable reduction in the capacity of the overhead coal bunkers.

The author considers with his present knowledge that the best overall efficiency and least maintenance cost is obtained by running the following combination:—

Water-tube boilers, economiser, chain-grate stokers, induced fan draughts. At 25 lb. of coal (rough engine slack) per sq. ft. grate area: Evaporation per sq. ft. of heating surface, 5.25 lb.; in-going gases to economiser, 450° F.; out-going gases from economiser, 300° F.; though it is quite possible to burn the same class of coal up to 30 lb. per sq. ft. of grate area with good economy.

The author has noticed that manufacturers have put forward for different capacities similar sizes of boilers, but with stokers having a larger grate area, so that some standard as to rating should be adopted. The standard adopted by the electric supply department at Sheffield is that the normal evaporation should be obtained by burning 25 lb. per sq. ft. of grate area with a chain grate stoker burning engine slack.

The author has lately installed some 8 ft. Class E. underfeed stokers to two water-tube boilers fitted with both forced and induced draught. The boilers were specified to evaporate 35,000 lb. of steam each from and at 212° F. The induced-draught fan h.p. on load is 55, giving 1.3" draught, and the forced-draught fan h.p. on load 80, giving 2" draught. Normal coal per sq. ft. of grate area is 33.5 lb. Evaporation per sq. ft. of heating surface is 5.25. The temperature of the in-going gases to the economiser is 518° F., and of the out-going gases 290° F. The results are:—Burning up to 47 lb. of coal per sq. ft. of grate area under the above working conditions the boiler evaporated 58,000 lb. of water per hour from and at 212° F., but the heat of the brickwork was so intense after the first hour's run that the rate of burning was reduced to 38 lb. per sq. ft. of grate area. The superheater was not designed to deal with this large amount of steam, the temperature being reduced from 150 under normal conditions to 110° F. The author thinks that this combination has a great future before it, and its limit will be determined by the ability of the brickwork, &c., to withstand the intense heat generated in the furnace with the above conditions.

There are many claims that the natural draught system is the right and most economical one, but it lacks flexibility, and makes it so dependent on atmospheric conditions, good coal, &c., and many instances are recorded where generating stations have been started with high brick chimneys, where at a later date fans have had to be added to secure the necessary flexibility and draught. The author is a believer in mechanical induced draught, and strongly advocates that care should be exercised to instal a fan or fans capable of dealing with the worst atmospheric conditions, and of dealing with sufficient gases for the maximum possible overload of the plant. Regarding the hot *versus* cold air systems of induced draught, it would appear that the latter should be the more economical, owing to the smaller power said to

be required to deal with the lesser volume. The author investigated this matter some three or four years ago, but could not satisfy himself that there was any very great benefit to be derived, besides which the cold air injector was expensive to manufacture and renew.

A decision with regard to the type of mechanical stokers is difficult to arrive at. The ideal stoker should be able to deal with clean nuts or smudge, should be able to get to full duty from banked fires in the shortest possible time, should be capable of doing 50 per cent. above its normal duty for short periods in case of emergency, should consume all combustible matter fed on it with the most efficient percentage of CO<sub>2</sub>, should be smokeless under all conditions, besides which it must be strongly built, reliable, and easy of access for the repair of the working parts or the renewal of the bars. These conditions are, of course, difficult of attainment in one stoker. For small grates there are many good and reliable stokers on the market in Britain, but with the larger grates now required the choice is focussed down to two or three. The chain grate has in the past done yeoman work, but it has its weak points, such as the difficulty of burning mixed slack and the difficulty of keeping an even covered grate, the prevention of unburnt coal being dumped, the extra labour in handling riddlings which filter through the grate before coking takes place, and it is unable to comply with many of the requirements set out above. However, when the improvements now being carried out on it are perfected, no doubt it will come much nearer to the ideal. The underfeed stoker, which has recently been enlarged and strengthened in its mechanical parts, has proved itself, from the author's experience during the last eighteen months, most satisfactory, and complies more nearly with the conditions before-mentioned.

The author therefore considers that the safest arrangement for a large boiler-house is to instal a certain proportion of the old reliable chain grate, which has proved satisfactory over a long series of years, and the remaining portion of the newer type, which, while being excellent from results obtained in a comparatively short time, has yet to prove its superiority over a longer period.

At the present time at Neepsend there are 3,000 tons of coal immediately over the boilers and 5,000 tons on the coal-storage ground. The method of storing coal depends on the quality. The author has experimented with various qualities and finds that rough slack obtained in the Yorkshire district and stored in large quantities is subject to spontaneous combustion. Consequently, nothing but screened nuts are now being laid down and stored in 500 ton lots. The heaps are ventilated and temperatures taken regularly. In this way it is anticipated that the coal may be left in the open for a period of years, and that the loss of calorific value will be only 10 to 15 per cent. The capital expenditure entailed in handling works out at approximately 15s. per ton of coal stored to about 6 ft. high. If, however, a better class of fuel be purchased, and the height increased, the cost will be proportionately less. This 15s. includes the provision of a complete scheme for delivering the coal from the wagons on to the storage ground and back again into the coal bunkers over the boiler.

Another system of storing coal where spare ground space is limited is to erect a silo and instal the Clayton or some similar system for extinguishing fire.

The following is a copy of the weekly costs sheet used in Sheffield, the figures being the actual ones for the week named:—

Particulars	Neepsend (32,000)	Sheaf Street (31,170)	Continued Stations (16,600)
Units generated			
Coal—Neepsend	104	11	23
Sheaf Street	77	3	12
Others	211	10	11
Water—Neepsend	24	3	5
Sheaf Street	125	1	1
Oil Waste and stores	4	4	1
Salvage and stocks	70	20	100
Engine Room Equipment	21	1	1
Boiler House Equipment	1	1	1
Buildings	1	1	1
Services	1	1	1
Lighting and Power	1	1	1
Total Works Costs	415	85	51
Maximum demand	8,111	1,611	9,917
Load Factor	35.5	14.26	33.5
Current used on Works	21,527	8,111	24,314

With regard to the suggestion made from time to time lately that large electric power-stations should be equipped

with by-product plants, it will, of course, be necessary to bear in mind that if such plants were installed for distilling the coal and making gas either for burning under the boilers or for driving a gas engine, the capital expenditure per kilowatt of plant installed would have to be considerably higher than it is at present, in an ordinary coal-fired steam turbine station. In looking through his present load curves, the author estimates that for 2,000 kw. of plant installed out of a total of 25,000 kw., it might be economical to provide by-product plant. This is about 8 per cent. of the total plant of a power-house, and this plant should be run at practically 80 per cent. load factor to make it a paying proposition. If a by-product plant were attached to a power-station, a much larger area would be required.

The problem of high superheat is looming in the not very distant future, and engineers and manufacturers will have to face a new set of conditions when a dull red gas is being passed through the steam-pipes and valves.

Finally, the author wishes to impress on all the great importance of a present-day boiler-house and plant; it is, in fact, of paramount importance, where more money can be saved than anywhere else in a power-station, to employ and pay highly-trained and capable men who can bring scientific knowledge to bear on the many important problems that present themselves for investigation. The Krieger car, equipped with a Naylor battery, also arrived from London by road.

### THE ELECTRIC VEHICLE PARADE

A DESCRIPTION of the cars taking part in the Electric Vehicle Parade appeared in our last issue, with illustrations of some of the cars. The four Edison cars came down by road, as did also a Stevens-Tilling petrol-electric car, towing one of the firm's new all-electric cars which was just got ready in time to send down in this manner. The latter is built on the same chassis as the petrol-electric type, a Tudor battery covered by a Renault type bonnet taking the place of the petrol engine and dynamo. It has a carrying capacity of from 3 to 4 tons.

### THE G.E.C. WORKS.

IN connection with the visit of the I.M.E.A. to the works of the General Electric Co. the opportunity was given by the Company to a large number of members of the Press to make a preliminary inspection of the works on Monday, and an extensive and interesting tour was made of the various factories at Witton and Edgbaston. In addition to the Engineering Works, the Fan Works, the Switchgear and Arc-Lamp Works, the Central Stores, and the Conduit Works, all of which were fully described in our last issue, the Carbon Works, which is the only factory in the United Kingdom at which arc-lamp carbons are manufactured, was open to inspection. The manufacture, which has required a large amount of experimenting to bring it to its present state of perfection, comprises about twenty-five separate processes. The raw material is obtained by the imperfect combustion of oil-fuel in a furnace. The vapour is cooled, and the deposited carbon is conveyed to rotary mixers, where it is moistened and reduced to a homogeneous semi-solid state. It is now pressed into blocks and fed into a forcing machine. From here it is forced out through a small circular opening of the same diameter as the finished carbons, and passes along a smooth table and under a revolving wheel which cuts it into lengths of about 5 ft. These lengths are then packed into cylindrical earthenware holders and placed in the baking ovens. The first of these is worked at a moderate temperature, so that the carbons are heated gradually and evenly. After being in this oven for some time the holders are transferred to the next oven, which has a slightly higher temperature, and afterwards to an oven with a still higher temperature, and so on until the highest temperature is reached. The process is then reversed, and the holders are gradually moved back to the first oven. The rods, which are now quite hard, are cut up into the requisite lengths, and are passed through an ingenious machine which sorts out any which are not of the correct dimensions. Another machine then points one end of each carbon. In the case of cored carbons, a central hole is left in the rods as they come out of the forcing machine. The soft core is now forced into place, and in a short time sets hard, and the carbon is ready for use. For certain classes of work, such as cinematography, the carbons are made with a copper core and an outer coating of copper. Both of these are electrolytically deposited, their object being to allow high-current densities to be used without undue heating of the carbons.

Luncheon, which was served at the Grand Hotel, Birmingham, was presided over by Mr. H. Hirst, the Chairman of the Company, who afterwards, in a short speech, deplored the present-day tendency to municipalise electrical undertakings. He also stated that the Company had absolutely no connection with any other firm, either in America or Germany, bearing the same name.

A visit to the Ilene Works at Edgbaston, which were also dealt with in our last issue, completed the interesting tour of inspection.

### THE ANNUAL DINNER

AT the Annual Dinner on Tuesday night an interesting speech was made by Dr. S. Z. de Ferranti in proposing the toast of the evening. He made a reference to the dissolution of the Industrial Committee of the Institution of Electrical Engineers, which indicated that the policy of the Institution Council in this matter was a subject of sincere regret to him. He referred to it as a "sad failure," he regretted that even personal friends of his on the Council held "views which he heartily detested," and hoped that it was still not too late to see a change of policy. Although he spoke guardedly, carefully choosing his words, it was clear that in referring to the I.M.E.A. as being conducted on right lines by its Council in doing its utmost in every direction conducive to the best interests of its members, he contrasted its policy in this respect with the older Institution, and left it to be inferred that it rested with the membership of the latter body to see that their views should prevail with its Council. Dr. Ferranti also referred to the portion of Mr. Chattock's Presidential Address relating to what he termed the nationalisation of electricity supply, and said that before the Chairman's ideals could be realised, a 25 per cent. efficiency in the conversion of the energy in fuel to electrical energy would be necessary, large improvements in the efficiency of transmission, and a lessening of the capital cost of transmission lines.

Mr. Chattock, in the course of his reply, asked members, at the Annual General Meeting to-morrow, to raise points on the discussion of the Annual Report, and to let the Council hear their views.

Interesting particulars of the progress of the Birmingham electricity department were made by Mr. J. F. C. Snell in proposing the toast of the "Electric Supply Committee of Birmingham," and by Councillor Ellaway, Chairman of the Committee, in his reply. The maximum possible output of the original Birmingham electricity works in Dale End had been one million units per annum. Now the output of the Summer Lane works is between 60 and 70 million units per annum, and a large station is being planned at Nechells, a suburb of Birmingham, with a capacity of 100,000 kw. and units of from 5,000 to 10,000 kw. capacity.

### DISCUSSIONS ON THE PAPERS

#### Commercial Development of Electricity Supply

MR. W. A. VIGNOLES read a short and excellent summary of his paper, in which he emphasised the importance of a corporation obtaining hiring and hire-purchase powers. In fact, he went further than he did in the paper itself, for he recommended that, if the dropping of the wiring and selling powers would facilitate the passage of the I.M.E.A. Bill, so that the hire and hire-purchase powers might be obtained, this should be done.

Mr. F. AYTON (Chief Electrical Engineer, Ipswich), who opened the discussion, said that at Ipswich they had been advertising ever since the inception of the undertaking ten years ago, and had come to the conclusion that any publicity work must not be of a spasmodic nature. The results from advertising were distinctly traceable and extremely good, but the effect noticed during the first year or two was small, and it was necessary to advertise steadily and continuously. One of the most valuable media he had found to be advertisements on trams, and one which had brought in best results read as follows: "Sunlight on tap is electric light. It makes the home more cheerful." He was in favour of short statements such as this, and adopted the mail card form of advertising in preference to pamphlets. His experience at Ipswich showed that it was possible to carry on publicity work at a very small cost indeed. For the year ending March 31st last he had spent only £141, which was the largest he had ever spent in one year, and for this he had produced and sent by post 23,000 different pieces of advertising literature. During the past seven years the load collected had increased by an average of 19.7 per cent. each year, whilst the average increase in sales was 25.2 per cent. He welcomed the suggestion of the formation of a Committee to create a central organisation for dealing with publicity work, as central station engineers had not the time

to do this work thoroughly. He fully agreed with the policy of encouraging wiring contractors, and agreed also with the Author that profits should be utilised for reducing capital expenditure. The curse of municipal electric supply in some places was the way in which the profits were "filched" from the undertakings to feed the rates. This in his opinion was the absolute negation of the municipal ideal. The only justification for municipal control was to supply electricity at such a low price that it was within the reach of every inhabitant. He believed the reason that the municipal representatives of the Publicity Committee had been practically thrown out was that the undertakings as a whole in the country did very little indeed to support this Committee. This attitude was entirely wrong, and all electric supply undertakings ought to be willing to assist handsomely in any organisation formed for publicity work. He hoped Mr. Vignoles would move a resolution at the Annual Meeting that the new Committee which he had suggested should be formed. If this were done it would mark the 1914 Convention of the Association as a starting point of a new era in electric supply progress. He would suggest that of this Committee there should be representatives not only of the Association, of the B.E.A.M.A., the Electrical Contractors' Association, and of the Institution of Electrical Engineers, but of every class of industry, including the Cable Makers' Association, in order that they could confer together and decide what should be done in the future.

Mr. A. H. SEABROOK (Chief Electrical Engineer, St. Marylebone) said that although he had not had time to read the Paper carefully, he agreed with it generally, but there was one point in it with which he disagreed. He placed the very greatest importance upon municipal undertakings which had wiring powers sticking to them and exercising them. Those undertakings which had not these powers should get them if they possibly could, not from the point of view of making of profits on the apparatus, but on account of the numerous points by which the servants of the undertaking could get into contact with the consumer and so extend the business. Rather than give up these powers if there was any obstacle to the co-operation which most of them were wanting, he would even suggest that any profits made by the undertaking on these sales should be pooled for the benefit of the electrical industry in the particular area. He was in entire agreement with the Author in the suggestion for the formation of what he might call a Development Committee on the lines of the Electrical Vehicle Committee, which had done such excellent work. Finally, he referred to the late Industrial Committee of the Institution of Electrical Engineers. Great things had been hoped for from this Committee, and it was undoubtedly by the Institution of Electrical Engineers that a central commercial organisation should have been created. It was, however, most disappointing that at the Annual General Meeting there were ten members of the Institution present, and the only ones who had anything to say in the way of criticism of the policy of the Institution were Mr. Hirst and himself—both members of Council. Nevertheless, it was well known that there was a strong undercurrent of dissatisfaction at the decision to disband this Committee, and it was astonishing to find the members taking so little interest. After all, the Council was elected by the membership, and it was the business of the individual members if they were dissatisfied with the policy of the Council to get the Council altered.

Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield), speaking with regard to the remarks in the Paper as to contractors, said he had had "some trouble" in Sheffield on this matter of dealing through contractors, but got along very well all the same. The trouble to him was how to effect sales through a contractor, and perhaps Mr. Vignoles would tell him how to do it. He advocated the policy of fixing the price for supply for any particular purpose at a figure which it might be anticipated would be profitable a few years after that supply was actually commenced. For instance, at Sheffield in 1902 he fixed a tariff for power at 1d. down to 0.6d., and that tariff was in force to-day, with the exception of the addition of the charge of £4 per kw. and 4d. for extra high-pressure supply. This same policy he recommended in connection with heating and cooking, and the soundness of it was demonstrated in the power load at Sheffield, which had increased since 1902 from 2 million to 26 million units per annum. With regard to mains extensions, in anticipation of the growth of the demand in all new streets he now laid two pipes, one to take the low-pressure main for the present demand and another to take the high-pressure main for the cooking demand, which would come along later. This he regarded as necessary because houses in Sheffield were beginning to take from 17 to 20 kw. each, and this could not be dealt with by the low-pressure mains. Also in this connection he only charged against any consumer the actual cost of supplying him; in other words, he calculated out the cost of the small main which would be necessary to supply a particular consumer, and if he was likely to be profitable at a reasonable period he was connected up. In this way some thirty or forty thousand pounds had been spent in street work for the future. He looked upon lighting now almost as a by-product; indeed, he would connect a lighting consumer even at a small loss, because that consumer was a very good advertising agent for the under-

taking, and would in all probability be the means of getting a dozen other consumers who would all be profitable. He had found the four-light radiator to be a back number now. It was quite easy to push the heating business in Sheffield because people were taking up 3 and 4 kw. apparatus. He had sent out many of these with the option of return after being tested side by side with gas stoves, but none of them had been returned. The figure of 15s. per quarter for cookers on hire was much too high a price, and very little business was likely to be done at that figure. He had fixed his rental at 4s. 6d. per quarter, and the difficulty now was to get cookers delivered in sufficient quantities.

Mr. E. E. HOADLEY (Chief Electrical Engineer, Maidstone) urged the Council to consider seriously the desirability of at once endeavouring to get hire and hire-purchase powers, and to try to get later on the fuller powers of the I.M.E.A. Bill. During the past six or seven years there had been a terrific lot of talk about getting these powers, and people outside would soon begin to think that the Association was an Association of Members of Parliament rather than of Engineers. It was very little use reducing the charge for heating and cooking to a 4d. when the consumer was told that he would have to pay £8 or £10 for a cooker, and this in face of the fact that the gas company would put one in free of charge at 3s. 6d. per quarter. A man must be a fool or a very keen enthusiast on electricity if he used an electric cooker. He agreed with the advisability of encouraging contractors. In Maidstone there were six contractors, and they were encouraged to such an extent that without the Municipal Supply Department they would all go out of business next week. In fact, the Department did all the canvassing and saw the work through whilst the contractor took the profit; but this, however, he did not object to, as the Department took the profit of the supply to the customer.

Mr. A. C. CRAMB (Chief Electrical Engineer, Croydon) disagreed with the Author on the question of show-rooms. These in his opinion were absolutely essential as a permanent place where the inhabitants could obtain information. He did not see any particular virtue in being able to say that the publicity costs on an undertaking were small. At Croydon £1,200 a year was spent upon the publicity department, £500 of which was in salaries. He agreed that a central publicity organisation was absolutely necessary, but Mr. Ayton was not quite correct in saying that the provincial representatives were thrown out of the Publicity Committee. The facts were that municipalities cannot subscribe to exhibitions and that sort of thing, and consequently it was not fair for them to continue to take part in the deliberations of the Committee if they did not do their share in the financial support. Therefore, the only graceful thing to do was to withdraw from the Committee. As a matter of fact, it was no good forming the proposed Committee until the I.M.E.A. Bill was obtained, because the only thing that municipalities could do at present was to spend money upon literature. Therefore the Association should concentrate upon getting the Bill through Parliament in order that they could spend their funds upon genuine publicity work. If amicable arrangements could be made with the contractors, he, and he believed, most other engineers, would prefer this rather than to carry on a sales department, but contractors could not be expected to hire out cookers and similar apparatus. There was a want of sincerity in this matter on the part of the Electrical Contractors' Association, and he urged the Association to stick to their Bill.

ALDERMAN SMITH (Liverpool) was warm in his praise of the Paper, and still warmer in his condemnation of Mr. Seabrook for not having read it. It should be unnecessary, he said, for Authors to read their Papers at the meeting, and if members did not read the printed copies they should not come to the meeting at all. He strongly protested against the suggestion that municipalities who transferred profits to relief of rates were "filching" the profits of the undertaking, and objected to Mr. Fedden's proposition that consumers should be connected at a loss. He did not mind facing an expenditure that might not be an immediate profit, but would have nothing to do with a consumer who would be a permanent loss. Similarly, he would have none of Mr. Seabrook's pooling of profits for the benefit of contractors, and if his own engineer held with that view he would try to clear him out.

BAILIE WILLOCK (Glasgow) joined issue with Alderman Smith. He quoted the famous Scotch saying that each herring should hang by its own head, and objected to profits being allocated to relief of rates.

Mr. J. H. BOWDEN (Chief Electrical Engineer, Poplar) said that nowadays an electrical engineer required also to be a financier, an accountant, a salesman, a cook, and a good organiser, or else he failed in his vocation. In fact, the manager of to-day must have a diversity factor of ten and a load factor of 200 per cent. He objected to the rateable value system of charging mainly on the ground that the assessments would be made by another department. He did not believe that he had yet heard the last word with regard to cookers, but he had now obtained quite a satisfactory one for £6 or £7, and anticipated doing a large business with it even in an East End borough like Poplar.

COUNCILLOR CROWTHER (Sheffield) expressed his great appreciation of the Paper, and strongly disagreed with Alderman

Smith as to the allocation of profits to relieve the rates. Whilst he was willing to work in conjunction with contractors, he objected to having his hands tied, and maintained that he should have the same freedom of action as any private firm. In answer to the Author's suggestion that sales departments were not necessary, he would like him to ask the Sheffield Gas Company whether they thought their showrooms and sales department of no use to them. He believed that electrical contractors suffered their greatest competition, not from the municipal electric supply department, but from firms, such as drapers, who took up electric wiring as a side-line.

Mr. Vignoles replied briefly to some of the points raised.

### Boiler House Plant

Our representatives at the meeting at Birmingham have telegraphed the following brief report of the discussion yesterday. A fuller report will appear in our next issue.

Mr. LACKIE (Glasgow), Mr. TAPPER (Stepney), Mr. R. U. BAILEY (of Summer Lane, Birmingham), and Mr. BRYDGES (Eastbourne) preferred heating feed-water with exhaust steam from auxiliaries, instead of live steam heaters. Mr. Lackie also referred to the necessity of steel steam pipes to withstand superheat. He had found coal-measuring chambers unreliable. By means of indicating instruments and special tests, he had saved 20 per cent. in coal consumption. He is now experimenting with Taylor stokers for quick steam-raising and also steam meters. Mr. BEAUCHAMP (West Ham) said that the only difficulty with suction ash-plant was dust, and he is overcoming this. Spontaneous combustion of coal stock was referred to. Mr. Bailey had only had trouble when the proportion of sulphur was high, and had successfully stored ten thousand tons, the largest heap being four thousand tons. Mr. Brydges had had two cases of fire with slack in heaps only eight feet deep; he now used pea coal, and there had been no spontaneous combustion, although the sulphur contents were high. Mr. AYTON (Ipswich) had had no trouble with Nottinghamshire slack in heaps twelve feet deep; he also described a bonus system for rewarding the boiler hands for low coal costs. Air heating was referred to by several speakers, and Dr. FERRANTI summed up the difficulties as insufficient heating on the one hand and burnt-out grate-bars on the other.

The above are only a few of the points raised in a long and interesting discussion. There were several other speakers, and a full report will appear in our next issue.

### ELECTRIC TRACTION NOTES

There was a net profit of £842 upon the Brighton tramways undertaking last year against £931 in the previous twelve months. The cost of the Brighton Corporation Acts of 1912 and 1913, however, have been responsible for £737 being charged in this year's accounts, which is an item of exceptional expenditure. Commenting on the demonstration with trolley omnibuses, the Tramways Manager and Engineer says that notwithstanding the overhead wires, these vehicles are very mobile in traffic, and he anticipates their complete success in Brighton.

The proposed purchase of the Bristol Tramways & Carriage Co. by the Bristol Corporation has been further discussed by the Council. There is considerable opposition by the Bristol Ratepayers' Association, who held a special meeting last week, but the poll of the citizens resulted in favour of the purchase.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

During the debate in the House of Commons last week on the Post Office vote of £15,151,830, Sir Henry Norman called attention to the slow progress which has been made in connection with the Imperial wireless telegraph chain. He pointed out that ten months have passed since the contract with Marconi's Wireless Telegraph Co. was ratified, and although it had been said that the sites have been acquired, power plants have not yet been approved. He suggested that the Marconi Co. is now rapidly establishing a monopoly in wireless communications which could not fail to be disastrous to the public interest.

After writing off £5,000 for depreciation and transferring £4,000 to general reserve, a dividend of 1s. per share and a bonus of 1s. per share, making 3s. for the year ending March 31st, is recommended by the Directors of the Peel Conner Telephone Works. The amount carried forward is £6,58.

In connection with a system of wireless telephony which is being developed by Capt. Colin and Lieut. Jeance of the French Navy, who some time ago succeeded in communicating between ship and shore over a distance of some seventy miles, experiments have been conducted recently between the Eiffel Tower and places at various distances away, and communication established with portable motor-car receiving sets sixty miles away. Conversation is also reported to have been carried on between Paris and Finisterre (300 miles) on the same system. It is, however, of special interest to note that on Friday, June 5th, one of their conversations was overheard at a small amateur station in England, at Louth (Lincolnshire) by Mr. E. F. Blaze. The apparatus necessary for the reception of wireless telephone messages is, of course, almost identical with that used for wireless telegraphy, and Mr. Blaze tells us that he happened to be tuning his apparatus

to pick up the usual 600 metre wave-length, when he was surprised to hear voices. He was unable to distinguish the words, but could make out enough to recognise that the French language was being spoken. Subsequently he heard of the experiments mentioned above, and wrote to Captain Colin, who expressed great interest and confirmed that a 600-metre wave-length was in use at the time, with a power, however, of 2 kilowatts. For a distance of about 300 miles with an aerial 40 ft. high and 110 ft. long the result is remarkable for daylight conditions. Mr. Blaze sends us some particulars of his installation, which is equipped practically entirely with home-made apparatus, including a tuning coil which cost about 2s. 6d. The receiving connections are shown in the diagram. The chief difference from the usual arrangement of loose-coupled oscillation transformers is the use of a 20-way switch instead of a slider. The primary consists of a 5-in. tube, 2½ in. diameter, wound with No. 20 S.W.G. silk-covered wire tapped off to the 20-way switch. The secondary, which slides within the primary, is wound with similar wire, and has the detector and telephones in series with it. Wave-length from 200 to 1,760 metres can be tuned in.

Communication with Alaska *via* Seattle was again down on the 9th inst., since when telegrams have been sent *via* Ashcroft. Repairs were effected on the 12th inst.—The route *via* Moulmein-Kanburi to Siam was restored on the 10th inst.

**The Bradford Electrical Exhibition.**—The preliminary prospectus has just been issued of the Electrical Exhibition which is to be held at the Manningham Lane Skating Rink, Bradford, from the 6th to the 24th October inclusive. For various reasons it has been found impossible to hold such an exhibition until the present year, one of the chief being that a suitable hall to accommodate the exhibits could not be obtained, and another that the electrical manufacturers were not disposed to participate in exhibitions run on the lines which have hitherto been the practice. The British Electrical and Allied Manufacturers' Association have now come to an agreement with the Incorporated Municipal Electrical Association as to the lines upon which exhibitions should be run, and the Bradford Exhibition will be the first to be held in accordance with the terms of the agreement come to. The exhibition is being promoted under the joint auspices of the B.E.A.M.A. and the Bradford Corporation, each party having appointed a number of their members to form a Special Committee of Management. The persons elected by the Bradford Electricity Committee are the Chairman (Ald. G. H. Robinson, J.P.), the Deputy Chairman (Cr. J. Haley), Cr. A. Ayrtton, and Cr. H. Seed, and the City Electrical Engineer (Mr. Thomas Roles); while the B.E.A.M.A. have appointed Mr. H. C. Palmer (the General Electric Co., Ltd.), Mr. B. Longbottom (Electromotors, Ltd.), Mr. C. Rodgers (Siemens Bros. Dynamo Works, Ltd.), and Mr. A. J. Ireland (the British Thomson-Houston Co., Ltd.), with the Secretary (Mr. D. N. Dunlop). Mr. James M. Freer, of the firm of Freer & Howard, Ltd., who have been appointed organisers and managers of the exhibition, is also a member of the committee. The Special Executive Sub-Committee consists of Mr. Roles, Mr. Dunlop, and Mr. Freer. It is hoped that exhibits of textile and printing machinery, machine tools, laundry machinery, &c., will be displayed under working conditions driven by electric motors, and every facility will be given exhibitors for making such displays. All persons interested should apply to Freer & Howard, Ltd. (Ludgate Chambers, 30-32 Ludgate Hill, London, E.C.).

# QUESTIONS AND ANSWERS BY PRACTICAL MEN

## RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,396.

The diagram represents a set of resistances connected up as a Wheatstone's bridge. Show how to calculate the combined

resistance between A and B, and the current that will flow through each arm of the circuit if a potential difference of 100 volts is applied between these points. "C. M. Y."

(Replies must be received not later than first post, June 25th.)

### ANSWERS TO No. 1,394.

The diagram shows the connections of a single-phase induction motor which is used for driving some rubber-grinding

machines. The main shafting is fitted with fast and loose pulleys, so that the motor can be started on no load. In spite of this, the belt has to be pulled round before the motor will start. The supply is single-phase, 50 cycles, 220 volts, and the motor is rated at 5 h.p., 935 r.p.m. Is there any way of getting the motor to be self-starting?—"SIMPLEX."

The first award (10s.) is made to "A. E. B." for the following reply:—

From the diagram given with the question it seems apparent to me that the motor already has a device for self-starting, shown in outline connected between the supply mains and stator terminals, but "Simplex" does not give any details of the internal connections of this. From the arrangement of leads I take it the machine has a three-phase winding on the stator, and that this starting device inserts a non-inductive resistance in series with one winding, and an inductance in series with the other winding, the third winding being, as shown, connected direct to main. The object of this is to split up the phase relations of the currents flowing in stator so as to obtain a near approximation to a three-phase supply, which in its

turn will produce a rotating field in stator. This rotating field cuts the rotor windings, and so causes it to rotate in the same direction as the field, which is the principle of all induc-

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

tion machines. When the motor is run up to speed the starting device can be cut out as the field will continue to rotate owing to the rotor reaction on stator windings.

Unfortunately the starting torque produced by this method is very low, and no doubt is not sufficient to overcome the inertia of the shafting, &c. Fig. 1 shows diagrammatically what I consider is the present method of starting, and its connections to stator. Fig. 2 gives another arrangement of connections which could probably be made by the same apparatus. This arrangement is, I believe, in fairly general use, and gives a much greater starting torque than Fig. 1. It has the advantage of full voltage across the terminals of stator, with the starting device connected as a shunt to the third terminal. Fig. 3 gives the vector diagram of this arrangement, the numbers 1, 2 and 3 corresponding to those given in Fig. 2. It will be seen this very closely approximates the vectors for three-phase supply, which are shown dotted. I think if "Simplex" will alter his connections to those shown in Fig. 2, he will overcome the self-starting difficulty.

The second award (5s.) is made to "H. J. E.," who writes as follows:—

There should be no difficulty in getting the motor to start against 30 per cent. full load torque, for a current equalling twice full-load current, provided there is sufficient displacement between the current in the starting winding and the current in the running winding. This displacement can be increased by placing a coil of eureka wire in series with the starting winding. Then by using an auto-transformer, some of the existing resistance in the rotor starter can be permanently cut out, thus allowing larger currents to flow in the windings without drawing an unreasonable current from the mains. The actual current demanded from the mains is less than the current in the motor windings by nearly the same proportion in which the voltage on the motor is reduced from that of the mains. The best ratio for the two currents, as well as the value for the resistance in the starting winding, will have to be found by experiment. The connections for the auto-transformer are shown in Fig. 4. The starter arm carries two brushes, both of which are connected to it electrically.

**The Faraday House Journal.**—The summer term issue of this bright little magazine contains full information as to the doings of old Faraday House Students. A special article is devoted to the Ljungström steam turbine, made by the Brush Electrical Engineering Co., which is now affiliated to Faraday House. An 800 h.p. Diesel engine is illustrated and described in another article, and a special contribution by Mr. J. T. Irwin deals with power transmission from the farmers' point of view.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published June 11th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

8,956/13. **Manufacture of Tungsten.** A. JUST. In this process a small percentage of another metal, such as vanadium, molybdenum, chromium, or tantalum, is added to the previously prepared pure tungsten, and the mixture is gradually heated up to about 2,000° C. according to the ordinary sintering process, or alternatively, the mixture is melted at a temperature of 3000° C. In both methods the maximum temperature must be maintained for some time to allow the tungsten to dissolve the added metal. The mixture is then suddenly cooled so that a crystalline solid solution of one of the above metals in tungsten is obtained. This product is then tempered in an electric furnace in a current of pure hydrogen or nitrogen, and is then found to be well suited for wire-drawing.

15,550/13. **Circuit Protection.** B.T.-H. Co. (G.E. Co., U.S.A.). On transmission systems, unduly high voltages are sometimes produced by various causes, e.g., lightning, and consequently discharges take place between the conductors of the system and the ground. Ordinarily, these discharges are oscillatory in character, and give rise to oscillations of energy on the system which may become dangerous. To obviate this possibility this invention requires that the discharge between the system and earth is localised at one particular place, by reducing the insulation value at this point. Also, the discharge must be made to take place through a resistance having approximately the critical value corresponding to the capacity and inductance of the system. The discharge is then aperiodic, and no oscillations of energy are set up in the system. The invention is applicable to underground and overhead systems. Two figures.

16,969/13. **Telegraph Receiver.** EASTERN TELEGRAPH CO., LTD., and J. SEFTON JENKINS. The invention relates to receivers in which an electric motor drives a perforator, and at the same time feeds the tape forward as required. It describes a method of maintaining the motor in phase with the signals received. This is effected by the use of a commutator, which, when the receiving apparatus is out of phase with the incoming signals, closes the circuit of an electromagnet through a relay. This electromagnet causes a ratchet wheel to rotate step by step through a pawl, and thus operates the arm of a rheostat, which corrects the speed of the motor. An auxiliary switch is also closed, which short-circuits a portion of the field or armature resistance momentarily, and thus causes a comparatively large temporary decrease or increase in the motor speed, and brings it into the correct phase. Five figures.

22,319/13. **Arc Lamp Carbons.** H. AYRTON. The negative electrode consists of a tubular rod of carbon, coated on the outside with a thin metallic film preferably of copper. The object of this film is to regulate the rate of burning of the negative carbon. By having the former of suitable thickness, the latter can be made to burn away at the same rate as the positive electrode. It is found that increasing the thickness of the film makes the carbon burn more slowly. Three figures.

26,802/13. **Electrostatic Separators.** J. KRAUS. In the usual type of these machines, trouble has hitherto been caused by the sparking of the electrodes. This disadvantage is obviated by using electrodes made of partially conducting material, such as wood, marble, or paper, in place of metal ones. The material to be separated is allowed to fall vertically between two or more charged electrodes. Endless conveyor bands passing over the surface of the electrodes serve to carry away the attracted material, which is discharged into conduits. Two figures.

26,906/13. **Dynamo Regulation.** R. BOSCH. A method of automatically regulating the current or voltage of a dynamo by varying the exciting current through a granular carbon resistance. The pressure on the granules is determined by an electromagnet, of which the strength is controlled by the factor to be regulated. An extra resistance is introduced into the circuit when the current rises beyond a certain limit. Six figures.

## Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: AYRTON, 12,082/13.

Distributing Systems, Cables and Wires, &c.: BEAVER and CLAREMONT [Cable manufacture] 13,602/13.

Dynamos, Motors, and Transformers: B.T.-H. Co. (G.E. Co.,

U.S.A.) [Motor control systems] 14,796/13; ALLMANNA SVENSKA ELECT. AKT. [Bar-wound A.C. machines] 8,565/14; SIEMENS SCHUCKERT. GES. [Starting and synchronising rotary converters] 9,225/14.

Heating and Cooking: MANN [Heaters] 11,993/13; CAMPBELL [Heating units] 15,014/13.

Ignition: LANGNER [Engine ignition system] 7,232/13; ELIA [Submarine mine ignition] 25,397/13; UNTERBERG and HELMLE [Magneto apparatus] 3,832/14.

Incandescent Lamps: HARRISON [Lamps] 12,054/13.

Instruments and Meters: EVERSHED & VIGNOLES and NEEDHAM [Electrical step by step motion] 28,234/13.

Switchgear, Fuses, and Fittings: SIMPLEX CONDUITS, LTD., and WATERHOUSE [Conduit system fittings] 12,115/13; WALKER [Junction-boxes] 14,848/13; FAHN and HUTTON [Switches] 17,275/13; MURRAY [Cut-outs] 17,345/13; DE OLAZABAL Y. EULATE [Thermal circuit breaker] 25,236/13.

Telephony and Telegraphy: AUTOMATIC TELEPHONE MFG. CO. (Automatic Electric Co.) [Telephone systems] 12,035/13, 12,162/13; HODGKINSON [Selectors] 12,100/13; GLOVER [Telephonic apparatus] 12,821/13; CARDWELL [Printing telegraph] 17,439/13; WESTERN ELECTRIC CO. (Woodward) [Telephone transmission system] 18,018/13; [Vacuum lightning arresters] 28,894/13; HICKMUTT [Telephone attachment] 4,397/14.

Miscellaneous: B.T.-H. Co. (G.E. Co., U.S.A.) [Air compressors] 11,996/13; SNOOK [Vacuum regulator for X-ray tubes] 12,256/13; B.T.-H. Co. (G.E. Co., U.S.A.) [Engine governor] 12,477/13; SOUTHGATE [Striking mechanism] 14,027/13; KIENZLE [Electrical machine tools] 24,686/13; SIEMENS BROS. DYNAMO WKS., LTD. (Siemens Schuckert. Ges.) [Spinning machines] 29,308/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, Motors, and Transformers: STORER [Dynamo machinery] 12,641/14.

Electrometallurgy and Electrochemistry: HANRIOT [Electrochemical reduction] 11,950/14; COUTAGNE [Nitride furnace] 12,057/14; A.E.G. [Welding] 12,479/14.

Ignition: BOURSIN [Petrol motor starting gear] 10,480/14; MICHELIS [Engine ignition] 12,347/14.

Incandescent Lamps: LEDERER [Gas filled lamps] 12,156/14, 12,157/14, 12,158/14.

Instruments and Meters: A.E.G. [Induction meter] 11,844/14. Storage Batteries: FORD [Accumulators] 10,100/14; SCHOLZ [Carbon electrodes] 10,171/14.

Telephony and Telegraphy: SIEMENS & HALSKE AKT. GES. [Automatic and semi-automatic telephony] 12,483/14.

Miscellaneous: NORMA CIE. GES. [Magnetic fixing devices] 11,993/14.

The following Amended Specifications may now be obtained:—

Electrometallurgy and Electrochemistry: PAUL SCHMIDT UND DESGRAZ G.M.B.H. [Electrolytic separation of copper] 3,722/13.

Miscellaneous: G. F. LYON [Electro pneumatic control] 3,757/13.

## Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

11,340 of 1900. **Electric Clocks.** M. FISCHER. A system of maintaining synchronism between a number of clocks and a master clock. The latter is driven by weights in the ordinary way, and each minute it releases an auxiliary wheel train which is also driven mechanically, and connected with the armature of a magneto. The subordinate clocks are connected by wires with the magneto coils, and are also provided with similar magneto machines. The armatures of the subordinate clocks thus move synchronously with that of the master clock, and the motion of these armatures is transmitted to the clock hands through springs which convert the abrupt motion into a continuous one. The claims also include for the use of a thin steel band in the master clock in place of the ordinary gut or steel wire. Eight figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: F. M. LEWIS [Clutch mechanism] 4,557/03; B.T.-H. Co. (G.E. Co., U.S.A.) [Central draught lamps] 4,831/07.

Ignition: T. WARDELL [Magneto] 4,339/08.

Instruments and Meters: A. BLANCHET [Induction type of A.C. meter] 5,010/02.

Switchgear, Fuses and Fittings: FELD BROS. & Co. [Plug cable coupling] 20,035/09.

Traction: J. O. HEINZE [Magnetic wheels for braking] 23,491/02.

Miscellaneous: C. L. BURDICK [Colouring process] 4,211/05.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 353. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**BOILER PLANT, &c.**—A booklet from Babcock & Wilcox, Ltd. (Oriol House, Farringdon Street, E.C.), gives illustrated descriptions of the well-known B. & W. water-tube boiler in its land and marine forms, and of the patented superheater which is used in conjunction with them. A portable pattern of boiler, arranged so that no piece exceeds 280 lbs., is made for foreign and Colonial work where transport is difficult. The firm's chain grate stoker is also described and illustrated, and further notes are given on steel chimneys, water-softening plants, feed-water heaters, steam piping and coal conveyors, and the interesting suction system of ash disposal which they introduced recently. A few illustrations are also given of electric crane installations, which represent a very extensive branch of the firm's activities.

**PERIOD DESIGNS IN FITTINGS.** An interesting booklet from Simplex Conduits, Ltd. (116 Charing Cross Road), entitled, "Notes on Period Designs in Electric Light Fittings," contains a series of articles on this subject by Mr. T. Birkett, late of the firm of Jesson & Birkett, whose business is now incorporated with that of Simplex Conduits, Ltd. The subject is treated historically, and the development and characteristics of the French, Dutch, English, and other "period" styles of decoration are treated in an interesting manner.

**COOKING APPARATUS.**—A new price list from the Brompton & Kensington Accessories Co., Ltd. (254 to 260 Earl's Court Road, S.W.), describes standard B. and K. cooking apparatus manufactured by them, including complete cooking stoves of several patterns, with combined ovens, grills, hot cupboards, and boiling plates, large cooking ranges, and separate hot cupboards and carving tables, as well as grills and toasters.

**WASTE-OIL FILTER.**—A catalogue from A. C. Wells & Co. (Midland Road, St. Pancras) describes the Wells patent waste-oil filter, which is made in several sizes. The oil is first syphoned off from a settling chamber, after which it passes successively through two special filtering pads.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**DOMESTIC USES OF ELECTRICITY.**—A series of pamphlets which are being circulated by the City of London Electric Lighting Co., Ltd. (1 and 2 Great Winchester Street, E.C.), call attention to electrical water heating appliances, vacuum cleaners, and fans. The company has a scheme for giving free trials of their "Bankside" water heater for one week.

**SEARCHLIGHTS.**—A supplementary priced leaflet of commercial patterns of searchlight projectors has been issued by Crompton & Co., Ltd. (Chelmsford).

**SWITCHGEAR, &c.**—A leaflet from Donovan & Co. (47 Cornwall Street, Birmingham) gives prices of starters, fans, knife switches, and ironclad switchgear and fittings.

**DOUBLE HELICAL GEARING.**—Some useful data regarding the strength and dimensions of double helical gearing is to be found in the two lists, Nos. 9 and 10, which are to hand from the Power Plant Co. (West Drayton, Middlesex). Illustrations are given showing helical gears applied to a variety of drives.

**HACK SAW MACHINES.**—A leaflet from the Fortuna Machine Co., Ltd. (Leicester), describes a new and improved form of hack saw machine with a special form of universal vice, which enables a great variety of different kinds of work to be handled. The machine has several interesting features, and permits of a wide adjustment of the length of stroke.

**TANTIRON.**—This is the name of a special alloy of similar nature to cast-iron, but with acid-resisting properties. Its applications are described in an illustrated booklet from the Lennox Foundry Co., Ltd., Tantiron Foundry, Glenville Grove, New Cross, S.E.

**Simplex Conduits, Ltd.**—The branch and departmental managers of Simplex Conduits, Ltd., have just held their annual conference at Southport, under the presidency of Mr. L. M. Waterhouse, the managing director of the Company.

### A NEW CONTINUITY GRIP

A SIMPLE and effective continuity grip for conduit fittings has been introduced by the Hemming Conduit Grip, Ltd. (174 Corporation Street, and 7A Dalton Street, Birmingham). The T fitting illustrated shows the arrangement adopted. The steel screws which make contact with the tube are in position in the fittings ready to receive the

THE HEMMING CONTINUITY GRIP.

tubes, and only need a half twist (to the left) to bring into operation the uncut portion of the thread which effectively grips the tube and sets up metallic contact. The driving home of the screws brings the hexagon head firmly on the base of the fitting, making a watertight joint. Even presuming the tubing to be used is undersized, it will only mean the uncut thread of the screw being brought more into play. The screw can be turned either with a box spanner or a screw-driver. The head of the screw is marked exactly over the machined part of the screw, so that if at any time the tube is to be released, all that is needed is to unscrew until the indicator faces the socket.

### RAILWAY STATION LIGHTING

THE photograph here reproduced shows an example of the effective station lighting arrangements which are being adopted on the Underground Electric Railways of London, Ltd., and represents the new booking hall at the Mansion House Station on the District Railway. This is

BOOKING HALL AT MANSION HOUSE STATION.

illuminated by Osram lamps in semi-indirect fittings known by the name "Latham." These consist of a japanned white reflector, opal diffuser, brass ring and chains. In another case, that of one of the arcades at the re-constructed Victoria Station, Osram lamps are used in 18 in. "Superlux" hemispheres, supported by aluminium painted iron rings.

**G.E.C. Head Office Fire Brigade.**—The Fire Brigade attached to the head office of the General Electric Co., Ltd., of 67 Queen Victoria Street, London, E.C., spent a very enjoyable time at Southend-on-Sea on June 5th, on the occasion of their annual outing. The party included the captain of the Brigade—Mr. W. H. Snowden—and Instructor Riley. Dinner was served at the Grand Pier Hotel.

## NEW CONDUIT FITTINGS

**A**MONG new conduit fittings recently introduced by the Sun Electrical Co., Ltd. (118-120 Charing Cross Road, W.C.), is a special junction box designed to meet the L.C.C. requirements for conduit work. These have lids placed internally and fixed by four screws; the edges of the boxes are machined to ensure watertight fit with the lid without

DOUBLE SPACING SADDLE.

packing. Another novelty is the form of spacing saddle illustrated here, which is for supporting conduit tube clear of the wall in damp situations. The base has a countersunk fixing hole sufficiently large to take a No. 10 wood screw, by means of which it is fixed to the wall. These are to take one, two, or three tubes.

## A LARGE SWITCHGEAR CONTRACT

**A**S announced in ELECTRICAL ENGINEERING, June 4th, page 304, the British Westinghouse Electric & Manufacturing Co., Ltd., have the contract for the high and low tension switchgear for the 11 sub-stations, in connection with the London & North-Western Railway Company's North London electrification. The panels on order at present total 258, comprising 129 H.T. panels and cubicles, 107 D.C. sub-station panels, and 22 low-tension A.C. and D.C. boards in the main station. The sub-stations are at Camden, Queen's Park, Stonebridge Park, Kenton, Pinney, Bushey, Dalston, Broad Street, Willesden, West End Lane, and Acton. There are three rotary converters in each, excepting at Broad Street and Acton, in which there are only two. The capacity of the six situated at Camden and Bushey is 1,000 kw., and of the remainder 750 kw. each. Thirty high-tension feeders come into the sub-stations, and there are also 18 H.T. outgoing feeders. The oil break circuit breakers are of British Westinghouse remote mechanically operated type, excepting in the case of Stonebridge Park, where they will be of the solenoid electrically operated type. Provision is made for phase separation throughout the whole of the structure, and each separate phase of the switch is contained in an independent tank, and in a separate moulded stone cubicle. The bus-bars are sectionalised, and each machine can be connected through isolating switches to either sections. Isolating switches are provided on each side of the main oil switches. All incoming feeders will be fitted with reverse current tripping relays, and all outgoing feeders and transformer circuits will have overload relays with time limit attachments. The rotary converter E.H.T. circuits will also be fitted with overload time limit relays. Each section of bus-bar will be fitted with horn type static dischargers combined with the usual resistances and isolating switches. The panels on which are mounted the instruments and handles for operating the oil circuit breaker, are situated on the floor level, and behind them are the cubicles containing the oil switches. These are linked to the operating handles which are mounted on the switchboard by means of levers and rods. In the case of the Stonebridge Park sub-station, the operating panels will also be on the floor level, and the switches will be electrically operated. The cell work is to consist of moulded stone. The slate panels of which the H.T. control board and also the L.T. switchboards are made will not be enamelled, but will be finished with a black marine finish. The low-tension panels, exclusive of battery and booster panels, which form the subject of another contract, deal with 100 out-going feeders and 31 rotary converters on the D.C. side. The rotary converter circuits are fitted with reverse current single-pole circuit breakers, fitted with a tripping arrangement for operation by speed-limiting devices on the rotaries. The track feeder panels which control both poles of one feeder are fitted with single-pole over-load circuit breakers for 2,000 amp., and two single-pole knife switches for the same current. Sector pattern moving coil ammeters are used, and have illuminated dials. The circuit breakers are of the well-known Westinghouse type "C" traction pattern. In addition to the above panels there are lighting and auxiliary panels in all the sub-stations, and in

## DIE CASTINGS

must not only "look" all right: they must BE all right: they must leave nothing to chance: there must be nothing experimental about their adoption.

"PRANA"  
DIE CASTINGS

(manufactured by the Firm who use them in their own business) are guaranteed to fulfil all these conditions.

*Accurate and Interchangeable.  
British-made—"Tough & True."*

**AERATORS, Ltd.** (Dept. EES) Upper Edmonton, London, N.

the power station a low-tension alternating current and low-tension direct current board are also to be supplied under this contract for dealing with the circuits feeding the auxiliary machinery, lighting, &c. The contract is estimated to be worth between £50,000 and £60,000.

## THE DEAN ELECTRIC HORN

**A** SIMPLE and compact electric horn for motor-cars and motor-cycles has been put on the market at a very reasonable price by the General Electric Co., Ltd. The sounding mechanism consists of a steel diaphragm, which is set vibrating by blows from a stud carried by the armature of a laminated electromagnet. The mechanism is similar in principle to that of the common trembler bell, but the con-

THE DEAN ELECTRIC MOTOR-CAR HORN.

struction is entirely different. The weight of the complete motor-car horn is 2½ lbs. if fitted with the standard 10 inch projector, or 2 lbs. with a 5½ in. projector. The finish is in black and nickel, or black only for fixing under the bonnet. The "Dean" horn is guaranteed for five years. It is water-tight and dust-proof, and the push-switch supplied with it differs from the usual push in that it is not a small button or plunger, but the upper cap effects contact over almost its entire surface, which is 1½ in. in diameter. A touch upon any portion suffices to close the circuit. A smaller pattern is made for motor-cycles.

**A Large Illuminated Hoarding.**—Siemens Bros. Dynamo Works, Ltd. (Dalston), have sent us particulars of an illuminated hoarding situated at Neasden facing the Metropolitan and Gt. Central Railways. This is illuminated by fifty 200 c.p. Wotan lamps, each in fittings throwing a maximum amount of light direct on to the hoarding. The experiment has proved completely successful, and this kind of illumination of hoardings should become very popular. The running cost is not excessive, and could be still further reduced by the application of half-watt lamps. The Neasden hoarding is under the control of Messrs. Hutching and Mills, and the current is supplied by the Metropolitan Railway from the Neasden generating station.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Australia.**—Electrically-operated car shed cranes for the Melbourne Suburban Railways. Consulting Engineers, Merz & McLellan, 32 Victoria Street, S.W. July 6th.

**London: L.C.C.**—Tenders are invited for five 1,500-kw. rotary-converters, fifteen main and two starting transformers for use therewith, and dismantling, removal, and re-erection of existing motor-generators. Also overhead 20-ton hand-crane. Tenders by July 14th. (See advertisement on another page.)

Tenders are invited by H.M. Office of Works for one year's supply of incandescent lamps. July 6th. (See advertisement on another page.)

**Lowestoft.**—A distributor is to be laid at an estimated cost of £190.

**New Zealand.**—The New Plymouth Council requires additions to a 2,300-volt sub-station switchboard, including three transformer panels, one coupler panel and four feeder panels together with instruments. A copy of the specification may be seen at 73 Basinghall Street, E.C.—The Oamaru Council proposes to raise a loan of £24,000 for an electric lighting scheme.—The Invercargill Corporation proposes to extend its electric lighting system at an estimated cost of £10,000.

**Skelton and Brotton.**—Tenders are invited for transformers, sub-station equipment, public lighting fittings, and overhead and underground cable. Consulting Engineers, Messrs. May & Hawes, Caxton House, Westminster, S.W. July 2nd.

**Sweden.**—Four transformers for the Royal Swedish Water-Power Administration. A copy of the specification may be seen at 73 Basinghall Street, E.C. Tenders by July 4th to "Kungl. Vattenfallsstyrelsens Elektrotekniska byrå, Regerings-gaten 45," Stockholm.

**Truro.**—The following are the items of capital expenditure anticipated in connection with the Council's electric lighting scheme:—Two 100-kw. generating sets, £3,650; overhead mains, £3,450; buildings, £1,300; services and meters, £350. Dr. J. A. Purves, of Exeter, is Consulting Engineer.

### Wiring

**Clogheen (Ireland).**—Tenders are to be invited for the electric lighting of the workhouse.

**Rhondda.**—Electrical installation at the Fever Hospital, Ystrad Rhondda, comprising 330 lighting points. Clerk to Council.

**Rochester.**—Tenders are invited for lighting the Corn Exchange buildings. Particulars from Mr. W. Banks, City Surveyor. Tenders by June 30th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Brighton.**—New concert hall on the site of the Aquarium.

**Dundee.**—Extensions to Dundee Post Office. H.M. Office of Works, London.

**Manchester.**—New technical school at Irlam.

**Pontypridd.**—Alterations and extensions at workhouse (£27,000).

**Ramsbottom.**—Warehouse and offices, Rose Bank Printing Works.

**Rochdale.**—Weaving shed. Builders, T. Ashworth & Sons.

**Sheffield.**—Extensions and alterations to Lodge Moor Hospital (£68,000).

**Sunderland.**—Extension to technical college.

### Miscellaneous

**Exeter.**—Twelve months' supply of electrical stores for the Devon County Asylum. Clerk, County Chambers, Main Street.

**Rotherham.**—Tenders are invited for tramway stores and materials, bitumen-covered and rubber-insulated cable, trolley wire, and ampere-hour meters. Tenders by July 8th. Particulars from Engineer and Manager, Electricity Works.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Devonport.**—The following tenders have been accepted:—Cables, Callender's Cable & Construction Co.; rubber-covered wires, Liverpool Electric Cable Co.; meters, British Thomson-Houston Co.

**Hindley.**—The tender of the British Insulated & Helsby Cables Co. has been accepted for cable.

**London: Hammersmith.**—The tender of Messrs. T. Wragg & Sons for cable-ducts is recommended for acceptance.—The tender of the British Electric Transformer Co. for six 100-kw. and a supply of other sizes of transformers, has been accepted.

**Manchester.**—The Corporation has accepted the following tenders:—L.T. switchgear, Ferguson, Pailin & Co.; cables, Johnson & Phillips, British Insulated & Helsby Cables, and W. T. Glover & Co.

**Salford.**—The tender of the British Westinghouse Co. for a 5,000-kw. turbo-alternator at £14,137 has been accepted. This acceptance is subject to the L.G.B. sanction, the inquiry having been held last week.

**Wallasey.**—The following tenders have been accepted in connection with the new generating station at Poulton:—Ferranti, Ltd., £1,304 for transformers; M. L. Prat (London), £1,084 for three steel chimneys.

The Corporation have made a contract with the British Thomson-Houston Co., Ltd., for twelve months' supply of their type R.H. A.C. meters.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £64 to £64 10s. (Last week, £64 5s. to £64 15s.)

**Agency.**—Morris & Lister, Ltd. (3 and 4 Palace Chambers, Bridge Street, Westminster, S.W., and Carlton Works, Lockhurst Lane, Coventry) who have hitherto been representing Nalder Bros. and Thompson, Ltd. (97A Dalston Lane, N.E.), to a limited extent for the sale of their manufactures, have now been appointed representatives in the London and country districts, heretofore worked by Frampton & Paine, whose agreement for the agency has now expired.

**The Bachelet Levitated Railway.**—We learn that the Directors of this scheme, upon which we commented in our Electric Traction Notes column last week, have decided not to proceed to allotment. The reason given is the disappointing result of the public issue.

**Liquidations.**—A meeting of the Hydro Electrical Gear Co. will be held at 11 Pancras Lane, E.C., on July 14th, to hear the liquidator's account of the winding-up.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Barnsley Smokeless Fuel Co.**—This Company, which has been formed for the purpose of erecting and working in co-operation with the Old Silkstone Collieries, a smokeless fuel plant capable of treatment 200 tons of coal per day at Barugh, Barnsley, under the patents of the British Coalite Co., is making an issue of £50,000 6 per cent. participating preference shares. It is interesting to note that the surplus of gas from the smokeless fuel plant will be taken by the Yorkshire Electric Power Co., and used at their Barugh station for the generating of electrical energy.

FOR  
**STEAM JOINTS**  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

## LOCAL NOTES

**Barrow-in-Furness: Electricity Accounts.**—There was a net profit of £513 on the working of the electricity undertaking last year, compared with £701 in the previous twelve months. The increased capital charges, however, are mainly responsible for the lower result. The revenue increased by nearly £2,500, and the number of units sold by some 300,000. The total working costs were 1·821d. per unit against 1·294d. per unit in the previous twelve months.

**Brentford: Gas Co. and Electricity Powers.**—We reported some time ago that the Brentford Gas Co. was granted powers by a House of Lords Committee to take transfers of electric lighting Orders within its area, and also power to apply to the Board of Trade for electric lighting Orders within its area where there is at present no statutory authority. The Metropolitan Electric Supply Co. at that time opposed, but unsuccessfully. The Gas Co. has now objected to the *locus* of the Electric Supply Co. in the House of Commons, and the point was fought before the Court of Referees on Thursday. Mr. Balfour Browne, K.C., for the Electric Supply Co., argued that the powers which had been granted by the House of Lords Committee to the Gas Co. constituted a form of competition, especially as regards bidding for the purchase of existing electric lighting Orders, whilst the power to apply to the Board of Trade for new electric lighting Orders brought competition a step nearer than it was at present. The Court, however, decided that the Metropolitan Electric Supply Co. would only be entitled to a *locus* if the Gas Co.'s Bill gave powers to actually compete in the supply of electricity, which it held was not the case. The *locus* was therefore disallowed.

**Dover: Kent Coal.**—A report has been presented by the Corporation Electrical Engineer dealing with a two-days' trial with Snowdown (Kent) coal. The evaporative power was found to be 10·69 lb. of steam per lb. of coal, against 10·6 lb. of steam per lb. of coal for the Featherstone washed coal now used. It was pointed out, however, that Kent coal caked into large masses which there was difficulty in breaking up, and therefore could not be burned very satisfactorily, nor could it be relied upon for a sudden call for extra steam. It was decided to make a further test with Tilmanstone coal, as the manufacturers of the boilers are anxious to see if Kent coal can be burned satisfactorily with chain-grate stokers.

**Hastings: Electricity Accounts.**—The electricity accounts for the year to March 31st show a net profit of £1,297, after meeting capital charges amounting to over £11,500.

**Horwich: Electric Supply.**—The South Lancashire Tramways Co. has informed the District Council that it has no powers to supply electricity in this district. The Bolton Corporation are to be asked for terms.

**Manchester: Development of Electricity Undertaking.**—On p. 314 of our issue for June 4th, we gave the financial result of the past year's working of the electricity undertaking. From the report of the Committee just to hand we notice that during the year supplies have been furnished to the following important consumers through sub-stations on their own premises:—Messrs. Armstrong, Whitworth & Co.; the Fine Cotton Spinners' Association; the Clayton Aniline Co.; Messrs. C. Macintosh & Co.; the National Wire Manufacturing Co.; Messrs. Slack & Brownlow; the John Nicholls Manufacturing Co.; Messrs. J. Byrom & Sons; the Great Central Railway Co. The efficiency of the distributing system as a whole was 84·49 per cent., being a decrease of 0·63 per cent. on the previous year. A contract has been placed with the Lancashire Water Cooler Co. for an installation of "open-type" water coolers, which it is anticipated will be a great improvement on the present plant. Contracts have also been placed with the Chloride Electrical Storage Co. for a traction battery at Dickinson Street, and with Bruce Peebles & Co. for additional converting plant. Although there has been a slight increase in the coal costs at Dickinson Street and Bloom Street, there was a slight decrease at Stuart Street, but taking the stations as a whole, there has been a slight increase. In the Street Lighting Department has to be noted the equipment of Stretford Road and the beginning of the electric lighting Order of important main roads.

**Middleton: Fixed Price System.**—The Council had decided to discontinue the supply of electricity to houses at a fixed annual charge, from the September quarter.

**Swansea: Electricity Demands.**—At the last meeting of the Electric Lighting Committee it was reported that there are increasing demands for power within a radius of one mile outside the Borough boundary. It was decided to approach the Board of Trade on the matter with regard to specific instances if the Board will not grant a sort of roving commission within this area without the formalities of an electric lighting Order.

**Wallasey: Close Estimating.**—At a special meeting of the Council last week attention was called to the very close approximation between the estimated and the actual figures for the new power-station at Poulton. The land had been put down at £18,000, whereas the actual figure came out to £12,673; buildings and works at £11,000, against an actual figure of £12,232; plant at £40,757, against an actual figure of £39,348. The result was an actual total of £64,253, against the estimated figure of £64,757.

**York: Electricity Accounts and a Showroom.**—The accounts of the Electricity Department for last year show an increase in revenue of £1,500, and an increase in expenditure of £3,500. Although at first sight this might seem to be somewhat poor business, the Chairman of the Electricity Committee reminded the Council that it was due solely to reductions in the charges made to private consumers and to the tramways. There was some criticism as to the necessity for retaining a showroom for the purpose of exhibiting electric cookers, but the reason for this was that the showroom where the fittings are housed is too small to show the cookers and fittings together. The opposition, however, succeeded in carrying its point, and the recommendation to retain the old showroom and offices in addition to the new ones was defeated.

## APPOINTMENTS AND PERSONAL NOTES

The proposal to raise the salary of Mr. A. H. Shaw, Borough Electrical Engineer at Ilford, from £500 to £525 per annum, has been deferred for further consideration.

The salary of Mr. T. Hall, Borough Electrical Engineer at Burton-on-Trent, is to be increased from £275 to £350 per annum, with a further increase of £50 per annum in 1915.

Mr. F. C. Sprigg has been appointed Electrical Engineer to the Turton U.D.C.

Mr. C. W. Jackson, Borough Electrical Engineer at King's Lynn, has been granted a bonus of £40 for extra work in connection with extensions during the past eighteen months.

The salary of Mr. F. R. Hobley, First Assistant Engineer in the Lowestoft Electricity Department, has been increased to £3 per week.

In view of the resignation of Mr. H. Love, Fourth Engineer-in-Charge at Hammersmith, who has obtained a similar appointment at Shoreditch, Engine-Driver J. E. Pearce has been promoted temporarily on trial to the vacant position at a salary of £180 per annum.

Mr. H. J. Groves Webb has resigned his position as Manager of the Apparatus Department of the Electrical Co., Ltd. (122 Charing Cross Road, W.C.), with whom he has been connected for the last five years.

A Chief Lecturer and Head of the Electrical Engineering Department is required at the Salford Royal Technical Institute. Salary £225 per annum. Applications by June 26th to Director of Education, Education Office, Salford.

## NEW COMPANIES

**SCOTTISH WELDING & ELECTRICAL CO.**—Registered by J. J. Weldon, 135 Wellington Street, Glasgow. Capital £1,000. Electrical engineers, motor and motor car manufacturers. (Private company.)

**NITRATE HEATING & POWER**, 110 Cannon Street, E.C. Capital, £6,000. To supply power and heat for the treatment of nitrates in the Republic of Chile, &c.

**PARK ROYAL ENGINEERING WORKS**, 34-6 Gresham Street, E.C. Capital, £20,000. To carry on the business of electricians, mechanical engineers, suppliers of electricity, &c., at Park Royal, Middlesex.

**MANCHESTER CABLE CO.**, registered by Jordan & Sons, 116 Chancery Lane, W.C. Capital, £1,000.

### SUMMARY

THE Birthday Honours List includes a knighthood for Mr. J. F. C. Snell. (Page 356.)

THE journey of the Krieger electric landulette from London to Birmingham and back, in connection with the Convention, is described. (Page 356.)

THE discussion on Mr. Fedden's Paper on boiler house equipment, &c., a summary of which was published in our last issue, is reported at length, and contains matter of an extremely practical and useful nature. (Page 357.)

A DESCRIPTION of the visit to the B.T.-H. works at Rugby, and of the same firm's meter works, appears on page 360.

MR. J. H. BOWDEN's Paper on the "Standardisation of Tariffs," read at Stratford-on-Avon on Thursday, advocated a tariff made up of a fixed charge and a charge per unit, but condemned the Norwich system as the most pernicious that had ever been introduced. Mr. Bowden explained his method of assessing the fixed charge by means of the assumed diversity factor for each class of supply. In the discussion, Mr. Bowden's system was severely criticised, and the debate centred chiefly around the rateable value system of charging. (Page 361.)

THE "Point Fives" debate, which lasted from midnight on Thursday to 2 a.m. on Friday, discussed many practical points. Mr. S. T. Allen (the Chairman) favoured standardisation of cookers, gave some figures to show the enormous advance of cooking under the 0.5 tariff, and raised an interesting point in connection with electric vehicle charging. Mr. Roles and Mr. Vignoles thought that there should be better representation of

the Point Fives on the Council of the I.M.E.A.; Mr. Seabrook said that he can keep up a supply of hot water more cheaply with electricity than with gas by the use of improved thermostats; Mr. Christie said he was applying to the L.G.B. for a loan to enable him to buy cookers and heaters for hiring out; Mr. Fedden explained some new and successful charges employed at Sheffield; and Mr. Grogan opposed connecting cookers across 400 or 500 volt outers. (Page 365.)

MR. H. RICHARDSON (Dundee) has been elected President of the I.M.E.A. for the coming year. At the annual general meeting on Friday an interesting statement was made with regard to the I.M.E.A. Bill, the establishment of a "Development Committee" to encourage the use of electricity was agreed to, and other matters were discussed. (Page 366.)

A NEW pattern of accumulator for dealing with intermittent supply to exhaust steam turbines is being introduced. (Page 368.)

A NEW protective system for isolating faulty feeders is described, with diagrams. The disconnection of the cable is effected through relays energised by ring transformers placed over the cables. (Page 369.)

THE annual inspection of the National Physical Laboratory was held on Friday last. (Page 370.)

AN Optophone, invented by Dr. E. E. Fourmier D'Albe, was shown at the recent Royal Society Conversation, and is dealt with in a short article. (Page 370.)

A NEW insulation tester is described in an illustrated article. (Page 371.)

A CORRESPONDENT desires further information as to the causes which led to the disbanding of the Industrial Committee of the Institution of Electrical Engineers. (Page 371.)

ONE of the specifications published last week describes a method of constructing an artificial line to balance a telephone transmission line loaded according to the Pupin system.—The Cooper-Hewitt mercury vapour lamp and a system of pneumatic-electric motor control are the subjects of two Patents which expire this week after lives of fourteen years. (Page 373.)

THE use of three-phase induction motors for braking is discussed in our Questions and Answers columns. (Page 374.)

THE Bill for the joint working of the Great Northern and City Railway by the Metropolitan and Great Northern Railway Companies has been withdrawn in consequence of the onerous conditions imposed by a Parliamentary Committee.—The annual congress of the Tramways and Light Railways Association is to be held at Newcastle. (Page 375.)

THE final report of the liquidator of the National Telephone Co. shows that the arbitration and liquidation expenses amounted to 1.32 per cent. of the sum realised. (Page 375.)

OUR Trade Section contains descriptions of an electric cooking stove and a commutator grinder. (Page 376.)

EXTENSIONS of generating plant are contemplated at Oldham and Rawtenstall, and a wet air filter is required at Rochdale.—A loan of £74,850 is being applied for at Walsall for a new electricity works. (Page 377.)

NEW supply schemes are under consideration at East Grinstead and Truro.—Profits are reported on the electricity undertakings at Lynn, Middlesbrough, Rugby, and Shrewsbury. (Page 378.)

THE General Electric Co. reports a trading profit of £157,898; a ten per cent. dividend is recommended.—The liquidation of the Consolidated Diesel Manufactures Co. is under consideration. (Page 378.)

THE Ilford Gas Co. is taking proceedings in the Chancery Division against the Ilford U.D.C. with regard to dealings in electrical fittings, and also the charges for power supply. It is alleged that in the first case money is being spent illegally, and in the second that preferential treatment is being given. (Page 378.)

THERE is a strike of electric wiremen at Liverpool. The answer to the wiremen's demands has been a reduction in wages. (Page 378.)

### ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 25TH.

*Institution of Electrical Engineers.*

9 p.m. Conversazione at Natural History Museum, Cromwell Road, S.W.

TUESDAY, JUNE 30TH.

*Wireless Society of London.*

8 p.m. At Institution of Electrical Engineers. "The Production of Continuous Waves by High-frequency Dynamo Machines," by Basil Binyon.

THURSDAY, JULY 2ND.

*Institution of Civil Engineers.*

8.30 p.m. Annual Conversazione at Great George Street, S.W.

### The London Electrical Engineers.

Headquarters (46 Regency Street, S.W.), open Sats. till noon. Rating Exam. for all Co.'s from 7 to 8.30 p.m. on Wednesday. (TO-DAY) THURSDAY, JUNE 25TH, C. Co., FRIDAY, JUNE 26TH, D. Co., SATURDAY, JUNE 27TH. Main body for Berehaven Camp parade Headquarters 12 noon.

### THE KRIEGER CAR'S RUN TO BIRMINGHAM AND BACK

A VERY successful trip from London to Birmingham and back was accomplished by the Krieger electric landaulette, which is equipped with a Naylor battery, in connection with the vehicle demonstration at the Birmingham Convention. The party of three started from the City at 6.40 a.m. on Monday, and the steady rise up the Finchley Road was taken at an average speed of 14½ m.p.h., the first stop being at St. Albans at 8.10, where Mr. Pauling of the Krieger Carriage Syndicate was picked up. The carriage then proceeded to Bedford, which it reached at 10.15. Here a stay was made, and the travellers partook of a much-needed breakfast, whilst the battery was given a charge of 206 amp.-hrs. The journey, which was continued at 12.59 p.m. from Bedford, through Northampton provided several opportunities of testing the capabilities of the car as a hill-climber, the most noticeable gradient being at Hill Norton, which was climbed at a speed of 10 m.p.h., with the battery yielding 130 amps. at 85 volts. A fresh charge of 200 amp.-hrs. was taken at the B.T.-H. Co.'s works at Rugby, and during the run down to Birmingham, which was reached at 8.23 p.m., the figure of 35 m.p.h. was attained on the gradient near Stonebridge. The following day the carriage was taken to Witton without any further charging, and in view of this fact it is worthy of mention that a speed of 35 m.p.h. was again attained on the Parade Ground. On Wednesday, after a battery charge of 183 amp.-hrs., the return journey was commenced at 3.0 p.m. The hill at Stonebridge proved less welcome now than on Monday, as it reduced the speed to 10 m.p.h., whilst the current rose to 115 amps. The B.T.-H. works were safely reached at 5.0 p.m., and another charge of 187 amp.-hrs. was taken, and the hilly road through Northampton to Bedford negotiated without any mishap. Next morning the battery was replenished after its duties of the preceding day by a charge of 200 amp.-hrs., and the journey was continued.

Leaving Bedford at 11.25 a.m. on Thursday, the car proceeded gaily along, only slackening pace at Luton Hill, where the current demand rose to 120 amps. at 85 volts for a short period, and reached Gillingham St. at 8.15 on Thursday afternoon.

### SIR JOHN SNELL

A GREAT honour has been done to the electrical engineering profession as represented by the Institution of Electrical Engineers by the conferring of a knighthood on its President-Elect, Mr. John Francis Claverton Snell, as well as to the recipient of the honour personally.

Mr. Snell, whose portrait we reproduce, rose to be President of the Institution very quickly, having been only elected Vice-President in 1911. He was on the Council first in 1909. He is a member of the firm of Consulting Engineers

of Preece, Cardew, and Snell, which he joined not long after resigning his position as Chief Electrical Engineer to the Sunderland Corporation in 1906, which he had held for ten years. He has been on more than one occasion prominently connected with Parliamentary work in the preparation of large electric supply schemes, acted on behalf of the London County Council in connection with the famous power Bills of 1905 and 1907, and was the leading expert for the Post Office in the arbitration proceedings concerning the sale of the National Telephone Co.'s business. Before going to Sunderland he was Resident Engineer to the St. Pancras Electricity Undertaking, and in earlier days was assistant to the late Major-General Webber.

### ELECTRIC POWER AT THE NEW HULL DOCKS

THE new Joint Dock of the North Eastern and the Hull and Barnsley Railways, which will be opened by the King to-morrow, involves a water area of 53 acres and a total length of quay of 8,162 ft., and is provided with an equipment worked entirely by electric power. No steam-power plant is installed, and the whole of the energy required will be supplied at 440 volts D.C. from the Corporation of Hull electricity works. Although the lock and graving dock gates and certain of the coal tips are actuated hydraulically, the whole of this plant is worked by electrically-driven pressure pumps.

The coaling appliances, which have a total capacity of 5,000 tons per hour, consist of five electric belt conveyors of a capacity of 800 tons per hour each, of which two are now being erected, in addition to two hydraulic hoists for 500 tons per hour. There are in all fifty-two electric cranes, comprising nine 10-ton cranes, four 7-ton cranes, thirty 3-ton cranes on the quay side, and nine 1½-ton travelling cranes on the roofs of the various warehouses. In the grain site, which is under construction, there will be eight underground electric belt conveyors, with a capacity of 120 tons per hour each, and six portable elevators, besides other electrically-driven appliances. The quay cranes will all travel on rails with a 15-ft. gauge, and have luffing jibs; six of the 10-ton cranes are fitted with portable elevators for discharging grain. The warehouse cranes are also fitted with special luffing gear.

It may be mentioned that the electric cranes were supplied some by Royce, Ltd. (Manchester), and some by Craven Brothers (Manchester). Electric capstans and other gear were supplied by Sir W. G. Armstrong, Whitworth & Co. (Newcastle). Other important contractors for the electrical portion of the work include:—Callender's Cable & Construction Co. (cables), The British Westinghouse Co. (switchgear), Crompton & Co. (arc lighting), W. Taylor & Co., Hull, and Falconer, Cross & Co., Newcastle (wiring), and Chamberlain & Hookham (meters).

## ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

### BOILER HOUSE EQUIPMENT

IN our last issue we reported the proceedings up to mid-day on Wednesday, including a summary, sent by telegraph, of the discussion on Mr. Fedden's Paper on boiler house equipment on Wednesday morning. We give below a fuller report of this discussion:—

MR. W. W. LACKIE (Chief Electrical Engineer, Glasgow) said that after a visit to some of the largest electricity undertakings in Canada and the United States last year, he had come to the conclusion that the modern boiler house was no longer a stokehold, but a boiler room, in the same sense as we now have an engine or turbine room, with ample natural light, and a minimum of dirt. The building should be at least of three storeys; the ash- and soot-handling plant should be on the ground floor; the first floor should contain the boilers proper; and economisers should be on the upper floor. His experience was that the larger the boiler unit one could obtain, the better. Until recently they had been accustomed to boiler units with a little over 4,000 sq. ft. heating surface, but, for sudden clouds, &c., it was very comforting to have one or two boilers of 8,000 or 9,000 sq. ft. heating surface available with steam up. They had found such boilers more efficient, and one man could look after a combination of such boilers as easily as he could look after the same number of smaller boilers. They had proved recently in Glasgow that nothing but steel should be used in steam pipe lines. The crown head valve on a boiler burst while the boiler was in commission, and if another valve had not been in series with the faulty one, serious consequences would have resulted. The Board of Trade inspector, after a thorough investigation, came to the conclusion that the trouble had been entirely due to superheat, and that steel was the only adequate safeguard. Bottom-emptying trucks, referred to by Mr. Fedden, were practically unobtainable in Scotland. Coal-measuring chambers had been found by them to be unreliable, and they used nothing but automatic weighing machines, one to each boiler. A few steam-driven auxiliaries, he continued, do away with the necessity of live steam feed-water heaters. On the question of coal storage he was of opinion that at least two months' stock should always be on hand, with such storage accommodation that uniform deliveries could be taken all the year through, and if anything a larger supply during the summer months. The modern boiler house should be equipped with instruments to show the amount of coal burned, the water evaporated, the steam passing to the generating plant, the draught, and in every way to have an equipment equivalent to the switchboard instruments in the engine room. Five years ago, at the time of the great trade depression, they realised in Glasgow that their coal consumption per unit was much higher than it should be, and immediately set about installing a considerable number of indicating instruments. These, along with special tests which were carried out, resulted in a saving in the coal bill for the year of some £10,000—practically 20 per cent. of the total cost—and yet it could not be said that there had not been reasonable care in the boiler house previously. The wear and tear of bucket conveyors for the removal of ashes was so great that these conveyors were being abandoned, and a suction ash plant had replaced them with most satisfactory results for the last six months. The cost of operating the suction ash plant worked out at about 5 units per ton—against which must be set the reduced cost of maintenance on moving plant and better conditions for the men. He noticed that Mr. Fedden recommended the combustion rate of 25 lb. per hr. per sq. ft. of grate area in boilers. In a recent test he had taken, four hand-fired boilers supply a 5,000-h.p. turbine, and burned coal at 30½ lb. per sq. ft., and generated 21,600 units. The lbs. of coal per unit were 3.41. He put on another boiler, making five, and reduced the coal burned to 21 lb., and the lbs. of coal per unit were 3.03—a reduction of 5½ per cent.; the draught in both tests was 0.4 in. water gauge. During the winter months, at time of peak, it was advisable to press the boilers much higher than the above rates. The cost per kw.-hour should always be given as so many lbs. of coal per unit, and the calorific value of the coal stated, or, better still, the number of B.Th.U. per kw.-hour. With reference to the question of equipping the power station with by-product plant and firing the boilers with gas, it had been stated on good authority that with coal below 10s. per ton, it would pay to do this on something like 8 per cent. of the total plant with a 20 per cent. load-factor in the power house; but with coal above 10s. it would not pay, owing to the enormous capital cost and area of ground necessary. One of the objects of his visit to America was to see how they tackled emergency peak loads due to fog or black clouds, more especially in Chicago and New York. Although they had batteries which they could put on to the central area of the city, the major portion of their lighting was on A.C. supply. He was shown

the Taylor stoker, which had been fully tested, and responded to sudden demands in a most remarkable manner, and was so much impressed with it that on his return it was arranged that two of his boilers should be equipped with it. The stokers are put under boilers which normally evaporated 24,000 lb. of water per hour, and the manufacturers have guaranteed that when the fuel bed of the stoker is maintained in a live banked condition, an interval of not more than 10 minutes would be required to bring the boiler up to the rate of steaming corresponding to an evaporation of 24,000 lb. per hour, and in an additional five minutes to 46,000 lb. The combined efficiency at 24,000 lb. is 72 per cent.; and the stoker should be capable of burning sufficient coal to evaporate a maximum of 58,000 lb. of water per hour. It was not their intention to run the boilers at these high rates for any length of time, but only to give sufficient time to get other boilers under way. In Glasgow and other large cities they were troubled with this question of sudden demands, especially during the summer, when a considerable number of the boilers were out for survey. In America he had also seen steam meters made by the General Electric Co. of America, and by the B.T.-H. Co. in this country. One of these meters was fixed on a boiler tested recently at Glasgow, and the indications were so satisfactory when compared with the measured water in the tanks that they were now equipping each boiler with a steam meter, the same as an ammeter on a generator. In Glasgow the cost of keeping banked boilers to meet sudden darkness was £5,000 a year. Mr. Fedden had mentioned 15s. per ton of coal stored as being the cost of the coal-handling plant. He (Mr. Lackie) had recently been looking into this question, and he had quotations which led him to think that stacking at the height at which they could do with Scotch coal, 7s. 6d. per ton gave an ample margin.

MR. J. W. BEAUCHAMP (Chief Electrical Engineer, West Ham) said that in most cities there was no market for ashes, and it was necessary to obtain a tip or to have them taken away. In London everybody paid a considerable sum; in some places as much as 2s. 6d. per ton was charged for barging the ashes to the lower reaches of the river. If the ashes were sold at the door, so to speak, the cost varied directly with the tonnage, but if one bought land and dealt with them by means of machinery, the cost consisted of two items: a fixed charge on the capital, and the small running charge. In the latter case the cost of ash removal dropped very much as the quantity increased. He had a suction ash plant which had not been working for a sufficient length of time to obtain any precise costs, but as far as he could see, the capital charges for the removal of 10,000 tons of ashes per annum from the ash tunnel to the slip where they were transported by barge or cart would come out to about 7d. per ton, and the electrical energy 2d. That 7d., however, would become 3½d. if the quantity of ashes were doubled. He had had one of these plants running for eight or nine months, and so far as he could see it was quite the most practicable way of removing the ashes. He used the pattern with a Roots exhauster, and no difficulty had been found with regard to repairs or erosion of pipes except at bends, where it was easy to replace them. The only difficulty found so far was with regard to the emission of dust, which depended upon the quality of coal used. This difficulty was being dealt with by the makers, who were putting in a separator. It might also be dealt with by using wet screens, as used for cleaning the air of buildings. The dust did not occur in the ash tunnel (the conditions in which were very much better than they were before), but when the air was blown out from the exhauster. One firm making this class of plant, he understood, was erecting a return pipe from the exhauster back to the hoppers, where the ashes enter the main conveyal pipe, to deal with surplus air drawn in at each opening where the ash enters. That reduced the load on the blower motor, and got rid of the dust difficulty to a very considerable extent. Where the clinker was hard he found it necessary to use a crusher. There were one or two minor disadvantages to the erection of the economisers above the boilers, neither of which, however, were sufficient to affect a big station. It was difficult to keep them full of water when the boiler was standing, so that there was a delay, when starting the feed pumps, before water appeared in the boiler. Moreover, it seemed reasonable to anticipate that corrosion would take place in the economiser at the air and water level, and it would probably be found necessary to make special arrangements to keep the economiser plumb full of water when the boilers were standing. Mr. Fedden's figure of £1 per ton for reinforced concrete coal bunkers agreed with his own experience at West Ham. He believed the authorities were divided as to whether coal stacks should be ventilated or tightly sealed. One point upon which the author had not touched was the provision of air required for the consumption of fuel in the furnaces. This in large stations was of enormous volume, and whether natural or suction draught was used, this air was generally obtained from all sources—through doors, windows,

and other openings, and during the winter weather when there was a tendency to restrict openings to the outer air, very acute draughts might be produced. He believed some work had been done in the direction of leading the heated air from the engine-room into the boiler for this purpose, and it did seem to be scientific and natural method tending to keep the engine-room cool and to provide the boiler furnaces with air which had already been raised to a fair temperature in the process of cooling generators. Another point was the provision of adequate space for the steam arrangements. Modern practice tended to do without duplicate pipes, &c., but it was often found that although all the chief items of plant were laid out with regard to their several needs, the steam piping was left to wind its way about the station as best it could, dodging columns and climbing stairs after the manner of flexible cable. In a very large station one might be justified in providing the main header with a special large chamber running lengthways between the engine-room and boiler house. If the chamber were enclosed it would act as a supplementary lagging, and, furthermore, there would be an added protection in the event of any serious explosion in the boiler house.

Mr. C. H. WORDINGHAM (Admiralty), referring to the use of special trucks at Sheffield, said he was surprised that more use had not been made of the "tippler." He was putting in an arrangement of that kind for a central station for which he was responsible, and believed it would give excellent results. It got over the difficulty of having special trucks, and avoided the danger of damaging the railway companies' rolling stock. His ideals as to merging the interests of gas and electric supply might not be very popular, but he thought that the position might be altered materially by the new system of combustion known as surface combustion, in which, instead of supplying the gas to the engine, it was supplied to the boiler, thus giving greatly increased efficiency, and a very large reduction in the size of the boiler, the latter enabling them to get steam-raising plant much more nearly of the same size as the steam turbine generating units.

Mr. W. C. P. TAPPER (Chief Electrical Engineer, Stepney) said that the author was fortunate in having a valley close by in which he could put his ashes, but in the part of London which he represented and which contained a population of 300,000 within an area of two square miles, it would be rather a difficulty to find such a valley into which to put his ashes. The £10 per kw. mentioned in the Paper for the capital expenditure on the whole station seemed so low that he could hardly think it included buildings and land as well as plant and machines. He was not at all sure that it was necessary to arrange the boilers at right angles to the engine room in order to get the necessary capacity; in Stepney he had found it possible to arrange the boilers parallel with the engine room for 5,000-kw. turbines. At Stepney also he had put a live steam feed heater into the hot well, and discharged the steam from the reciprocating pumps through the heater, thus retaining all the heat and discharging the oily contents of the water into the drain. He was now putting in a turbine-driven rotary feed pump, and the whole of the exhaust from this would be turned back into the hot well. He had been the first to instal the Prat induced draught system at Stepney, having put in four chimneys dealing with eight boilers. In that case the chimneys worked on what was called the cold blast system, and they had worked entirely satisfactorily. In the extensions at Stepney he was putting in the later type of Prat chimney with the in-circuit system, i.e., a fan draws a certain proportion of the boiler gases and passes them back under pressure into the chimney. The general arrangement would be a boiler with a travelling grate stoker and forced draught under the stoker and induced draught above it, thus giving a balanced draught on the bars, each boiler complete with its own chimney.

Mr. YORATH LEWIS (British Niclausse Boiler Co., Ltd.) invited the members to inspect the Britnic boiler equipment which had recently been installed at Southend. By this system of boilers he claimed that it was possible to evaporate anything from 150 to 200 lb. per hr. per sq. ft. of ground space occupied. Mr. Fedden had set out in the Paper what he considered to be the best combinations of plant available in this country to get what he considered to be the best overall efficiency and least maintenance cost. The second combination was indicated as likely to have the greater future presumably because it had been able to give an overload capacity of 65 per cent. for about an hour. There were many features of this equipment which he would like to discuss in detail, but he would only mention in passing the draught pressure of 3.3 in. required for working at normal load, and that to provide this, both induced and forced draught plants were required aggregating 85 h.p. He submitted that a superior combination could be presented of Britnic specialities throughout in units up to 60 or 70,000 lb. of steam per hour. The boiler would evaporate at 6.75 lb. at normal load, and 9½-10 lb. at 40 per cent. overload per sq. ft. of tube external heating surface. The superheaters would be located immediately above the boiler tubes. The steam temperature would be 600° at all loads without distress on long periods of working, and the steel tube economisers would be capable of being kept clean internally and externally. The gases would be discharged into the chimney at 360°. Low-pressure forced draught would be included

with mechanical stokers of liberal grate area capable of ready adjustments to burn any class of coal from the richest to the poorest, absolutely without smoke and with the least amount of excess air at any rate of adjustment between three-quarter load and 40 or 50 per cent. overload, for two or three hours without undue distress on the bars. There would also be low-pressure forced draught fans, situated in the basement under the firing floor, working with a low air pressure in the ash pit.

Mr. A. ATKINSON (Clarke, Chapman & Co.) advocated the use of the Wodson boiler made by his firm.

Mr. G. D. SEATON (Richardsons, Westgarth & Co.) insisted that plant should be tested by an independent engineer to ascertain whether it came up to its steam guarantees.

Mr. R. U. BAILEY (Resident Engineer, Summer Lane, Birmingham) favoured the use of steam auxiliaries. In the event of an interruption to the supply, the motor-driven auxiliaries at once failed, and this, of course, greatly complicated the restoration of supply. He also thought that the small steam plant was less liable to breakdown than motors when continuous running was necessary, and the employment of exhaust steam for feed heating purposes gave a very high economic result as the latent heat of the steam returned to the boilers. Mr. Fedden had stated that when burning 25 lbs. of rough engine slack per sq. ft. of grate area, 5.25 lbs. of water would be evaporated per sq. ft. of heating surface. This amount of coal per square foot of grate area was exceedingly low for such high evaporation. In general practice he thought 32 lbs. per sq. ft. was more likely to be obtained when working a water-tube boiler at its rated normal capacity. The figure of 5.25 lbs. of water evaporated per square foot of heating surface was exceptionally high, as, in applying this duty to a standard 43,000 lb. per hour Babcock boiler for comparative purposes, the duty would be 32,455 lbs. per hour from and at 212° F., which was 35.5 per cent. over duty. He therefore did not think that these figures were consistent with conditions obtained in common practice. Mr. Fedden had given a further set of figures relating to the duty obtained with the underfeed stoker, and it was intensely interesting to find that the boiler duty could be increased 65 per cent. above normal. It was very unfortunate that Mr. Fedden had not given the thermal value of the fuel used nor the lbs. of water evaporated per lb. of coal, so that an idea might be formed as to the thermal efficiency of the boiler working under these conditions. Mr. Fedden had enumerated the difficulties which existed with chain-grate stokers, and undoubtedly when burning a fine slack the handling of the riddlings was a matter which had to be taken seriously into consideration, as this amount was, he thought, between 3 and 4 per cent. of the total coal passed over the stoker. These riddlings had a very much reduced calorific value as compared with the main fuel, due to the volatile matter being small, but they had a high carbon value. The general practice was, he believed, to throw these riddlings periodically back again into the hoppers, but this had the effect of spoiling the fires and upsetting uniform combustion. At Summer Lane station two underfeed stokers were employed almost entirely burning these riddlings, and it was found that this method was highly economical. It would, of course, be impossible to use a chain-grate stoker entirely for this class of fuel, as having practically no volatile value there would be little or no flame, consequently the temperature of the arches would be below that necessary for igniting the fuel. In connection with storage of coal, Mr. Fedden had omitted to state the most important point of all, viz., that it was undoubtedly the presence of sulphur in coal which occasioned spontaneous combustion; the sulphur, which was usually present in the form of iron pyrites, readily disintegrated, and caused heat to be generated. Coals free from sulphur might be stacked with a certain amount of latitude. At Birmingham they were at present carrying a stock of 10,000 tons, the largest heap being 4,000 tons. This coal stock was made up of 3-in. nuts at the base, and graded through the various sizes of nuts to shallow screenings at the top. The depth of the stack was 12 ft. The object of this grading was to allow any local heat which might be generated to be readily dispersed through the interstices of the coal. The chance of firing was, of course, greater at the base, due to the weight of the coal above. A smaller heap made in this way, containing 1,500 tons, had been down for about three years, and they had up to the present been unable to detect any appreciable rise in temperature above that of the atmosphere. They also had a still smaller stack of 700 tons which had been standing for about six years, the heap consisting entirely of nutty screenings, and to-day practically showed as high a calorific value as when put down, the crust only being weathered. This latter stack was put down at the same time as other stacks of coal drawn from other collieries, which readily gave trouble owing to spontaneous combustion, and they had since found by analyses that the coal standing to-day was the only coal free from sulphur. He noticed that Mr. Fedden had purchased his coal to a rigid specification, and that any coal which was found to be at all below the calorific value specified had its price reduced proportionately. This latter point he did not think at all satisfactory, as coal people were apt to take advantage of this, and dump upon one coal for which they could not find a market and which was cheap at any price to be rid of. Mr. Bailey further

recommended that a record of the calorific value of the coal used should be included in the weekly cost sheets, so that the B.-Th.U's per kw. hr. could be noted and expressed as the "percentage thermal efficiency of the station."

Mr. W. R. WOOD (Underfeed Stoker Co.) gave the results of some tests in which the evaporation was 8½ lb. per hr. per sq. ft. of heating surface; the escaped gas in the boiler had a temperature of 530 deg., and the escaped gas in the economisers had a temperature of 310 deg., whilst the efficiency was approximately 85 per cent. From this he maintained it could be argued that high rates of combustion under proper conditions did not reduce the efficiency of a boiler plant. Mr. Lackie had pointed out that with four boilers working at 30 lb. of coal per sq. ft. of heating surface the efficiency was lower than with five boilers working at 25 lb. Mr. Lackie had, however, introduced another factor, viz., the increased heating surface, and he would like to know whether Mr. Lackie attributed the falling-off in efficiency at higher rates of combustion to imperfect combustion or to the difference in the heating surface.

Mr. J. K. BRYDGES (Chief Electrical Engineer, Eastbourne) said that it would have been preferable if the engineers had stated their difficulties first, and that the manufacturers' representatives should have followed them in the discussion, to explain why the difficulties had occurred. With reference to live steam feed heaters, he suggested that the increase of temperature mentioned by Mr. Fedden could have been produced entirely with the feed pump exhaust. He believed there was at hand an apparatus for pre-heating the air before it got into the boilers. It had merely to be put into the flue so that the only cost was a small capital outlay. He was contemplating putting down more boilers, and would like to hear the experiences with these pre-heaters; he believed Mr. Bowden, of Poplar, had one. It had been suggested that the pre-heating of the air caused excessive burning of the grate bars, and that it also necessarily meant there must be a closed ash pit or loss of air carried to the grate. He had found it absolutely impossible to store slack coal in heaps of more than about 8 ft. deep, although his bunkers were 21 ft. deep. He now used pea coal, and although it contained sulphur, he could stock this coal 18 ft. deep. He had fitted tubes through which he could drop thermometers, and had not found the rise of temperature to be more than 10 to 12 deg. He agreed with those speakers who thought an evaporation of 25 lb. per hour per sq. ft. of heating surface was plenty. A higher rate might do with a vertical tube boiler, but not out of a B. & W., without trouble with the hog tubes at such a high duty. The cleaning of horizontal tube boilers was very expensive, because nowadays when the inspector came round he wanted every cap taken off every tube. With a vertical tube boiler, however, it was possible to get at all the tubes with very little trouble indeed. The only difficulty with a curved tube boiler was that the inspector wanted a ball dropped down every tube. He kept two balls, one slightly smaller than the other, for this purpose. He had found that the length of time for cleaning a boiler varied from ten days to three weeks, according to the type, and this should be considered in putting in new boilers.

Mr. F. AXTON (Chief Electrical Engineer, Ipswich) asked if any members had had experience in getting rid of ashes by means of the water-pipe system similar to that used for the ejection of ashes at sea. This might get rid of the dust difficulty. When using natural draught it might be an advantage to arrange the openings on the four cardinal sides of the boiler house so as to get the maximum effect by opening them on the side where the wind was blowing. As to storing coal, he used Nottinghamshire slack and stored in heaps not less than 12 ft. deep, and had never had any trouble with firing. The coal, however, was not strong in sulphur content. He was always having trouble with the links of B. & W. chain-grate stokers; the small projection on the side of each link, to fit into the space between the adjacent two links, burned off in a very short time. At Ipswich he was trying a bonus system for economy of coal in the boiler house. A value for the coal costs was fixed for each quarter and the bonus was given for all coal consumption which improved it. The bonus was distributed among the firemen, trimmers, drivers, switchboard attendants, and the shift engineers.

Mr. R. HAMMOND said that he had recently been for some months in South Africa, and had examined the large new power station of the Transvaal Power Co. at Vereeniging, which would ultimately have a capacity of 80,000 kw. When he first saw it he thought the works were not in operation, but subsequently found out that although they were burning 1,000 tons of coal per day there was not the slightest amount of smoke to be seen coming out of the chimneys. That was his testimony of what was actually being done with the Prat system, and if Mr. Fedden's station worked with the same efficiency he was not surprised that he had got the costs to so low a point as was seen by the Paper.

Mr. S. UTTING (who represents the Prat system in this country) said he was very pleased to see that Mr. Fedden had come to the conclusion that 25 lbs. per square ft. of grate area was a good figure. There were, however, times when that figure could not be upheld, and when higher rates of combustion must be adopted, which meant more active draught. Mr. Fedden had given the results of some of his tests, and said

that the out-going gases to the chimney were at 300° F. There were frequently, in central station work in England, cases in which the gases were at 240—300° F., and there were several central stations on the Continent where they were getting even lower. To get this with natural draught would need a chimney 400 or 450 feet high. Mr. Tapper was the first central station engineer in this country who had experience of the Prat system by which cold air was injected into the chimney in order to induce the flow of the main current. Nine or ten years ago Prat developed another means whereby he used the main flow of the gases in order to create this induction. Such a plant had actually been designed for Birmingham, and had been working for some time. Mr. Prat could tell them that if with his most efficient "out of circuit" system 100 units were required, then his "in-circuit" system would take 75 units. If it were dealing with cold air it was necessary to deal with the main product of combustion representing 100 per cent., plus the cold air required for injection, which was no small amount, and consequently the apparatus must be bigger. In the Tramways Department in Sheffield this plant was working on two boilers, with a similar arrangement to that now adopted by Mr. Fedden; the boilers were side by side, and had 30,000 lbs. per hour normal evaporation. From some test figures he had, it would be seen that the load corresponded to about 7 per cent. over-load. The plant was burning 6,420 lbs. of coal per hour, and there was only an induced draught fan, no forced draught, and the simple Prat "in-circuit" system, the h.p. on the fan being 21. The plant at Birmingham was tested three or four weeks ago, and the average of three tests worked out at 9,600 lbs. of coal per hour; the average draught was from 31 to 33 mm., and the h.p. was 35. That did not compare very unfavourably with Mr. Fedden's figures, and it constituted an admirable arrangement where the rate of combustion per sq. ft. of grate surface must be for ordinary conditions something in the neighbourhood of 30 to 35 lbs. per sq. ft. or more.

Alderman Dr. H. GERVIS (Brighton) said he thoroughly, absolutely, and entirely agreed with Mr. Fedden as to the employment of highly-trained technical men, but it was the most difficult thing to do to convince a council—at least it was so in the South of England—where the democracy was most unwilling to pay for brains. As Chairman of the Brighton Lighting Committee, he could say that his Council would, as a rule, pass large sums for plant and apparatus with three minutes' discussion, but if he wanted a rise of salary of a few shillings for a highly scientific and skilful employee it meant two hours of acrimonious debate.

Dr. S. Z. DE FERRANTI, speaking first with regard to air heating for boiler fires, said that theoretically it was perfectly right to heat the air for combustion under the boiler, but in practice little satisfaction had been obtained from this process. The plant was invariably put in too small, and the result was that instead of the air being properly heated up to a fair equivalent of the temperature of the outgoing gases, a very poor result was obtained. With only a moderate efficiency from the plant, however, there had been very great trouble with fire-bars, which with hand-stoking had stood, but with various forms of mechanical stokers there had been nothing but trouble. A fire-grate depended for its existence upon the lowering of the temperature of the bars by the incoming cold air. Slagging appeared to be the worst trouble, and the surface of the bar was eaten away.

Mr. W. M. SELVEY (Sheffield) said that at present coal-buying was left largely to the coal broker, and it had always been a grievance of the engineer that he had no voice in buying coal. The real reason why engineers had no voice in this was that they could not sample the coal. It would be necessary more and more in the future to keep boilers at right angles to the engine-room, to make these boilers even bigger, and to put the economiser on top of the boiler to fill the whole of the available space that there was on the ground plan of the boiler. Even with this they would have serious difficulties in keeping the boiler house alongside 20,000 kw.-units. The question of the boiler house in this respect was entirely one of the stoker. The size of boilers had not increased; in other words, they had rested by the way, and now that it was time to move it was found necessary to go to America for stokers. Although the Taylor stoker was quite good, however, he regarded it only as a passing phase. Two things were wanted: first, a perforated platform to support the coal; and, secondly, a means of driving this platform. Developments in this direction had already been made, and particularly in the direction of separating the function of the platform from the function of the driver, and this tended to make the arrangement flexible in the same way as the governor made a turbine flexible. Finally, with regard to gas-making, he would like to point out that the bulk of coal was carbon. When electrical engineers could assist the gas industry by using boilers in which gas coke could be used efficiently, then it would be time to think about whether they could do anything in conjunction.

Mr. S. E. FEDDEN was unable to reply to the discussion owing to the shortness of time.

After being entertained at luncheon by the Coventry Corporation, the members visited the various works

on the programme, the majority of them going to the Daimler Motor-Car Works and the Coventry Electricity Works, both described in our issue of June 11th. Others proceeded to Rugby to view the Willans or the B.T.-H. Works. A description of the former also appeared in our issue of June 11th.

### THE RUGBY WORKS OF THE BRITISH THOMSON-HOUSTON CO.

The works at Rugby of the B.T.-H. Co. were visited by a party of fifty-seven.

The erection of the works was commenced in 1900. The present works occupy a site of some 39½ acres, and consist of

design of B.T.-H. apparatus, it is only possible to mention here a few of the most important of the company's manufactures. The Curtis turbine which has been built at Rugby since 1904 is well known as exemplifying all that is best in the impulse type. They are made for capacities of about 40 h.p. and upwards, both for high pressure and mixed pressure. The company's motors, both for direct- and alternating-current circuits, are stocked for all ordinary voltages and in the sizes most in demand. They are famed for their simple robust construction and reliability. B.T.-H. rotary converters are built for capacities up to 3,000 kw. for any standard voltage up to 1,500 volts D.C. on 25 cycles, and 750 volts D.C. on 50 cycles. They are of liberal design, and are suitable for reactance, booster, or induction regulator control. The company has also patented a two-part split-pole method of controlling the voltage ratio on their 25-cycle machines, which is free from the defects inherent in the three-part pole system, and has met with great success wherever installed. A large number of different types of con-

FIG. 1.—TURBINE SHOP AT B.T.-H. WORKS, RUGBY.

72 buildings covering a total ground area of 477,174 sq. ft., with a total floor space of 800,000 sq. ft. Sidings are provided connecting with the London and North Western and Midland Railways, and the handling of material in the works yard is taken care of by a locomotive and two travelling cranes, while light shunting is provided for by electric capstans. A 40-ton electric lift is provided to transfer loaded trucks to and from one of the buildings, which is at a lower level than the rest of the works. Material inside the buildings is handled by electric cranes with capacities up to 40 tons; a comprehensive narrow-gauge railway system also connects all parts of the works. The fire extinguishing equipment is very complete, and patterns are stored in a special fireproof building.

The heating of the buildings is mostly on the hot-air blower system, air being drawn in from outside, passed over steam heated coils, and distributed throughout the buildings.

The machine-tool equipment is thoroughly up to date, consisting chiefly of English makes, with some American and Continental machines, all of which, with the exception of a few pneumatic and hydraulic machines, are electrically worked. A large number are driven by individual continuous-current motors, the small machines being grouped and run from short lines of shafting. Power is obtained from the company's own power house, which contains plant aggregating 4,760 kw., the machines installed ranging from slow-speed reciprocating sets to high-speed turbo-generators. The thorough testing and inspection of all apparatus in the finished state, and in the various stages of manufacture, is a special feature to which a great deal of attention is given. The company has also factories at Willesden and Coventry, to which their switchgear and electrical instrument factories respectively have been removed. The Coventry works also take care of the manufacture of electrical heating and cooking apparatus. The company's employees number nearly 6,000, of whom 4,013 are employed in the Rugby works and offices.

Although many distinguishing features are embodied in the

FIG. 2.—1,500-KW. 25-CYCLE 300-R.P.M. 600-VOLTS COMPOUND-WOUND INTERPOLE ROTARY CONVERTER FOR L. & S.W.R.

trollers are manufactured by the B.T.-H. Co., suitable for traction, haulage, machine tools, printing presses, &c. In addition to the numerous hand-operated controllers, the company manufactures many automatic starting and regulating equipments for

use with all types of A.C. and D.C. motors operating under the most arduous conditions. One of the best-known products of the B.T.-H. Co. is, of course, the Mazda drawn wire tungsten lamp, which was introduced by the company in 1911, and the more recently introduced nitrogen-filled "half-watt" lamps.

The visitors commenced their tour of the works by an inspection of the assembly department, where they were shown direct-current and alternating-current induction motors of the "Three in One" type. This is a recent development of the B.T.-H. motor design, whereby a single motor can be converted from protected to enclosed ventilated or drip-proof types by simply adding suitable covers. They proceeded to the turbine erecting and testing shop illustrated in Fig. 1 and saw 48 turbo-generator sets, ranging in size from 33 kw. to 6,000 kw. in various stages of construction. The machines on test in this shop included a 3,000-kw. turbo-alternator, a 2,000-kw. alternator for Kawasaki, a 1,000-kw. single-phase turbo-alternator for Bournemouth and Poole, a 300-kw. D.C. turbo-generator and a 100-kw. turbo-generator for the City and Guilds Institute, and a blower driven by a direct-current motor running at 3,000 r.p.m. Two 750-kw. rotary converters for the L. & N.W. Rly. were also on test, as well as two 1,500-kw. rotary converters for the L. & S.W. Rly. The number of these machines at present going through the shops amounts to 87, including 18 1,500-kw., nine 1,200-kw., 31 1,000-kw., and 29 750-kw. In another shop a large number of railway motors for the Central Argentine Railway were seen. There are over 200 of these motors, each of 250-h.p. capacity, at present going through the shops. A visit was also paid to the controller and rheostat factory, where a complete line of hand-operated rheostats, and a large motor-operated rheostat were seen, together with a complete line of B.T.-H. crane, mining, and tramway controllers. A new line of protected and totally enclosed starting rheostats, and an experimental train control equipment are also on view. The visitors then proceeded to the lamp factory, where they were shown the various processes in the manufacture of Mazda drawn wire and half-watt lamps.

### THE B.T.-H. METER WORKS

It is to be regretted that only five members and visitors availed themselves of the opportunity to visit the meter works at Coventry, as although in size they cannot compare either with the Daimler, the B.T.-H. Rugby works, or the Willans works, there was much of interest to see there. The works, which were started about two years ago, were previously the Humber cycle works. They are in three buildings, and are arranged for the accommodation of 1,500 employees.

In the manufacture of the D.C. meter, the copper cup is turned from a bar of electrolytic copper, and then finished on a special lathe of smaller type. It is then amalgamated and treated by a special process, which ensures that it is absolutely pure, as in the B.T.-H. meter the whole of the cup, and not merely the edge, is amalgamated, and is in contact with the mercury. The spindle is made in an automatic machine, which produces three complete spindles a minute, drills it either end, and hobs it. The hardened steel pivots are polished, examined under a microscope, and then fitted in the spindle, and the spindle is then fitted in the cup. The mercury chamber in which the cup revolves is made from drawn brass, turned out, and is nickel-plated to prevent the mercury from attacking it. The whole is then fitted together, the magnets screwed on, after which the magnets are magnetised with everything in position. This process of magnetising simply consists of hanging the magnets on a copper bar through which a current of 8,000 amperes is passing. The dials and cases are then fitted.

In the case of the A.C. meters the magnets have to be magnetised before the parts are assembled, and to "age" them they are afterwards placed with a copper disc rotating at 2,500 revs. per minute between the poles. An interesting feature in the manufacture of the A.C. meter is that the coils have no formers and no cheeks. A different machine is used for each size of wire, and the wire is simply wound on a metal former which is slipped out after winding. Paper is placed between each layer of wire. After winding, the coils are varnished and baked solid.

Besides meters, ammeters, voltmeters and wattmeters, relays, Tirrill regulators, the contactor gear for electric trains, heating and cooking apparatus (including electric irons), and arc lamps are made at these works, and speedometers for motor-cars also form a considerable portion of the works' output.

On Wednesday evening, after the return to Birmingham, the Lord Mayor and Lady Mayoress gave a reception and dance in the Council Chamber. The guests were subjected to a close scrutiny as they arrived by the Corporation officials, assisted by Mr. McArthur Butler, so that no suffragettes should be admitted, and the result was a most enjoyable evening.

On Thursday morning the Association proceeded to Stratford-on-Avon in motor char-a-bancs and motor buses, and after a welcome by the Mayor, Mr. Bowden's Paper (which follows, in abstract) was discussed.

### THE STANDARDIZATION OF TARIFFS

By J. HORACE BOWDEN (*Chief Electrical Engineer, Poplar*).

IF it were possible to so arrange tariffs as to produce an income exactly equivalent to expenditure, such tariffs, if conceived on equitable bases, would undoubtedly be ideal, but there are contingencies which prevent the consummation of the ideal, notably the fluctuations in the price of coal and maintenance of plant, buildings, and mains. It is practical to create a contingency fund in order to equalise these fluctuations over a period of years, but even if such a course were adopted the prudent manager must always provide a sufficient margin to show a surplus at the end of the period. The ultimate disposal of this sum should be at the discretion of the local Council, but as the amount should be comparatively small, and of little effect in reduction of rates, the author submits that a special fund be created from which the cost of special public improvements could be taken, which would be monumental of the benefit to the community of electricity undertakings apart from their legitimate sphere of public utility.

The author does not advocate the borrowing of money to supply cooking and heating appliances on hire; provision should be made out of revenue for any expenditure that may be necessary in this direction.

The Local Government Board now allows periods from twenty-five to fifteen years for the repayment of loans on account of mains, and the London County Council has fixed the maximum period at twenty-five years. Twelve and ten years are considered suitable periods for services and meters respectively. Why these bodies, in their wisdom, should have fixed these arbitrary periods is beyond the conception of the author. The law of continuity of supply renders it imperative that mains, services, and meters shall always be kept in a perfect state of efficiency, and there does not appear to be any valid reason why the extreme limit allowed by law for repayment of the loans for these purposes should not be granted, namely, sixty years.

#### The Tariff Ideal.

While it may be true that the laws of expediency govern private enterprise, it should never be lost sight of that Municipal enterprise is governed by the laws of equity. No argument, however specious, will alter the fact that it is inequitable to supply to one class of consumer at a loss which is to be recouped from another class.

The future practice in electricity supply is undoubtedly that which will enable an authority to assess an annual charge for declared requirements, irrespective of the purpose to which power may be applied, or to the extent that such power may be used. The present-day practice renders it essential that a secondary charge must be made in order to restrict unlimited use of power, for the sole reason that certain running costs are entailed in the production of electrical energy, although there is a possibility in the near future that these running costs will be entirely eliminated by the sale of by-products, &c., gas and coke products for steaming purposes, or for gas turbines or other gas-driven plant, and further revenue may be obtained from the sale of exhaust steam for heating, &c. It is in the interests of all concerned to standardise this secondary charge, and for this purpose the Association known as the "Point Fives" came into being. The charge of 0.5d. per unit carries with it, in modern undertakings, a sufficient margin over and above running cost to allow for fluctuations in price of coal, and provision against all contingencies such as breakdown of electrical machinery and failure of distributing and feeder cables.

#### The Norwich, or Rateable Value System.

No more pernicious system than the rateable value system for assessing the primary charge has ever been introduced into electricity practice. Its only attributes are those of expediency and simplicity in its application to domestic property. Apart from the insurmountable objection to this system raised by the fact that tenants in houses similarly assessed may make most divergent demands upon the resources of an undertaking, there are many serious obstacles to the attainment of permanent adoption.

Take the instance of property in a decadent area; as the value of property decreases the demand for electricity would naturally increase from the fact that originally in the possession of one family, it degenerates into tenements of several families.

Another instance is that of a tenant obtaining possession of property at a reduced rental because of installing electricity. One of the strongest arguments in favour of the supply is that the necessity for internal decoration of house property is con-

siderably lessened, and it is now quite practical for a tenant to make an agreement with a landlord not to require internal decorative work during a specified term of tenancy at a reduced rental.

The assessment on dwellings at and under £20 per annum is generally much lower than the better class, due to compounding by the landlords, yet this class of tenant will make a greater demand in proportion to rateable value than the possessor of a residence with a number of rooms, landings, and offices occasionally lighted.

Again, the working class is generally more prolific than the genteel class, and, having a greater number of mouths to feed, cooking operations are carried out at more frequent and irregular hours of the day, thus raising the diversity factor for their class.

In the Poplar area there are 3,259 houses rated over £20 per annum, and the author estimates that an average use of energy could be made by each tenant of 3,000 units per annum under present conditions of supply. But there are 19,866 houses rated at and under £20 each, having a prospective use of 1,000 units per annum under present conditions.

But when the case of the shop-keeping class is considered, there does not appear to be any justification whatever for the system. Shop rent is chiefly dependent upon environment, and premises in a main and important thoroughfare may command double the rent of similar premises in a street of minor importance, whereas the latter may require greater illuminating power than the former in order to attract attention.

The assessment of licensed premises is generally considerably greater than other business premises making a similar demand for light.

The application of the rateable value system to factories is perhaps more appropriate than to any other class of supply, and the rating officials would probably welcome an innovation whereby the horse-power installed would come directly under their notice, but it is doubtful if the consumer would duly appreciate a rise in rateable value consequent upon his increased demand for electrical power. It appears to be a curious fact that the only equitable application of the rateable value system would act as a deterrent to the adoption of electricity because, as a natural sequence to the installation of, say, an additional 100-h.p. motor, the Electricity Department would apply to the Rating Department to make an increased assessment on the property of that particular consumer. The strongest advocates of this system would strenuously oppose the application to factory supply, and but few would attempt to apply it to business supply of any description.

But apart from the inherent impracticability of rateable value as the basis of fixing a charge for universal supply, there is the objection of handing over to another department the onus of fixing the primary charge for electricity. It is only a natural sequence for that department to undertake the collection of such charges, and the engineer would then become subservient to the dictates of the Finance and Rating Departments, and his province is one of attending to his machinery alone. Once the element of business is eradicated from electricity supply, the present high status of the profession will be considerably lowered.

### Diversity Factors for Assessing Fixed Charges.

The accepted definition of the diversity factor in a supply of electrical energy is "the sum of the consumers' maximum demands, divided by the combined maximum demand upon the system." When energy was principally used for lighting purposes, this factor was of considerable importance, as by its use it was practical to fix the annual assessment, and divide it into a daily use of the consumers' maximum demand. Assuming that by dividing the standing costs of an undertaking by the maximum demand upon the system the cost was found to be £16 per kw., and the ascertained diversity factor was 1.5, and the selling price of energy 1d. per unit, then the charge to the consumer was  $(£16 \div 1.5 \times 365) \div 1d.$  per unit for one hour's use per day of each kilowatt of maximum demand, the result being 8d. per unit, all further use being charged at the selling price of 1d. per unit.

The maximum demand system became practically standard for lighting uses of electricity, but the great difficulty in explaining its operation to the consumer sufficed to act as a deterrent to progress, and, as a sacrifice to simplicity, departures were made by reducing the primary charge with a corresponding raising of the secondary charge, or by the institution of a flat-rate based upon average use. In this manner the inherent equity of the original system was nullified, and the consumers at once became divisible into "bad" and "good" from the supplier's point of view. As good consumers must of a necessity compensate for bad consumers in any solvent business, the cultivating of electricity supply became subject to the laws of expediency, and as progress has been made in power supply and more recently in heating and cooking and other uses of electricity, the

law of equity has apparently been more and more lost sight of.

It is to be expected at the hands of the administrators of the supply so to adjust tariffs as to conform with the laws of equity. This can best be done by studying the conditions of each class of supply in each individual area upon its own merits, and estimating the relationship of the demand for each class to the actual maximum demand upon the system.

Apart from public lighting, internal business lighting, and what is known as the 100 per cent. load factor power supply, all other demands are more or less subject to the application of diversity factors. In Poplar, which is an industrial area, the following scale has been adopted, viz.:—

Nature of Demand.	Diversity Factor.
Public Lighting ... ..	Unity.
Business Lighting, internal ... ..	Unity.
Business Lighting, external ... ..	1.2
Intermittent power ... ..	2
Domestic Lighting, general ... ..	2
Domestic Lighting, occasional ... ..	8
Cooking and Heating ... ..	20

The maximum demand occurs between 4.30 and 4.40 p.m.

**Public Lighting.**—At this particular period the whole of the public lamps are in lighting, and at first consideration a unity factor appears to be correct. But it must be taken into consideration that, in some of the streets, mains are laid from which little other demand than for public service is made, carrying with it capital and administrative charges; therefore a slightly higher charge has been considered admissible to cover this cost.

**Business Lighting.**—The charge is assessed on watts installed, it being assumed that all internal lighting will be in use at the period of maximum demand. It is not the usual business practice in Poplar to light up externally until later in the day, and by dividing the ascertained standing cost per kw. by 1.2 any discrepancy lies in favour of the undertaking.

**Intermittent Power.**—Every works of any importance installs a certain amount of power as stand-by both in regard to number and size of motors. As a general rule 75 per cent. of the total kilowatts installed may be taken as the normal load, and the diversity factor of two has been taken as the relationship of the normal load to the maximum demand, as it is generally found that motors are slackening down gradually from 3 p.m., therefore at 4.30 to 4.40 p.m. not more than one-half of the connected normal power load is likely to be in use at that time.

It has not come within the province of the Poplar undertaking to deal with any 100 per cent. load factor supply, but the author has no hesitation in stating that any tariff based on a greater diversity factor than unity, would not produce results equivalent to those obtained from an intermittent supply on the bases quoted.

**Domestic Lighting.**—A distinction has been drawn between general and occasional lighting. The demand has been assessed upon watts installed, and occasional lighting is generally understood to include bedrooms, cellars, offices and upper landings. In fixing the diversity factor at two for general lighting regard was had to the fact that under ordinary circumstances the whole supply would not be in use at 4.30 p.m. In purely residential areas it would perhaps be unwise to allow for this margin of diversity. For occasional lighting the factor of eight is not unreasonable, and certainly admits of many additional points being installed which otherwise would be left out.

**Cooking and Heating.**—For cooking and heating it is obviously unfair to make the assessment on watts installed. The cooking outfit in one residence may include heating elements that are not called into requisition for every-day use, whilst in another daily use may be given to all the elements comprising the outfit. The type of cooker also has some bearing upon the assessment; a rapid heater, although involving a greater demand, is used for shorter periods, and, therefore, the diversity is increased. However, there should be no difficulty in framing a scale to allow for these varying conditions.

In assuming a diversity factor of twenty, three peak times had to be considered. The daily power peaks occur at 11 a.m. and 3 p.m., as nearly as may be, and, by the lighting peak converging upon the power load, which produces the maximum demand, a third peak is created in early winter at 4.30 p.m. or thereabouts. It can be reasonably assumed that cooking operations will not commence until after 11 a.m., nor be continued after 2 p.m., and the acquisition of a load to fill the gap between 11 a.m. and 3 p.m. is most important. It may, however, be assumed that the demand will be felt at 4.30 p.m. when preparing afternoon tea and the workers' evening meal, but the loading required for the preparation of these meals is considerably less than for the mid-day meal. Taking everything into consideration, it is not unreasonable to assume that less than one-twentieth of the capacity of cookers installed will be in use at 4.30 p.m. on that particular day when the maximum demand occurs.

In dealing with this question, it has also to be borne in mind that the cooking load will almost invariably, in an

industrial area, be largely supplied through mains practically unaffected by the demand for power, therefore the additional load imposed upon the system will involve capital expenditure principally on plant and buildings.

The author submits that the price of electricity when in general use for lighting and cooking should not exceed 3d. per unit, competing with gas at 2s. 6d. per 1,000 cubic feet, or thereabouts. In fact, in order to beat gas competition out of the field, this price should permit of the inclusion of hire of cooker, heaters and installation, in order to encourage liberality of use necessary to ensure the supply being profitable.

Bearing in mind the bases of charges laid down in this paper, the following example will illustrate the position:—

A moderate-size residence of £26 per annum rateable value required a gas service for cooking and lighting costing approximately £10 per annum.

To replace this, twenty-two various lights and a 24 kw. cooking outfit were installed. The cost of the service, meter, and wiring installation was £20 5s. 4d., and the cooking outfit £8 10s. 8d. The total number of units supplied during twelve months was 3,128.

The annual assessment was, on the Poplar tariff, as follows, dividing £8 per kw. by the diversity factor in each case:—

0.552 kw. lighting at £4; 0.32 kw., occasional lighting at £1; and 2.4 kw. cooking at 8s., amounting to £2 14s. 7d. The cost of energy, 3,128 units at 0.5d., amounted to £6 10s. 4d., making a total charge of £9 4s. 11d., or 0.71d. per unit. The hire of the service (12½ per cent. on cost) amounted to £3 12s. 11d., bringing the total bill to £12 17s. 10d., or 0.99d. per unit.

It will be seen that the supply of energy alone compared favourably with the cost of gas, but in order to obtain the supply it was necessary to expend £28 16s., which, of course, must be expected to produce an adequate return.

The author has no hesitation in stating that for prudent reasons the annual charge on account of this expenditure is greater than the anticipated cost. The basis of ten years' life of service, meter, installation and cooker is undoubtedly too short, but regard was had to the accepted terms of ten and twelve years granted by sanctioning authorities for meters and services, and the unstable type of cooker then in the market. Promise is now given of a reliable cooker at a cost of £6, and experience shows that the average life of services will probably reach thirty years, and that twenty years may be presumed as the life of wiring installations and meters of first-rate workmanship. Furthermore, by dealing with this class of work on a greatly extended scale, the prime cost may be expected to be considerably reduced.

Viewing the situation from this standpoint, the service charges are amenable as follows, viz:—

	£	s.	d.
Service ... .. say 3	30	years	... 2 0
Meter and Installation ... .. 16	20	years	... 16 0
Cooker ... .. 6	10	years	... 12 0
Interest at 3½ per cent ... .. 25			17 6

Annual Charge ... .. £2 7 6

making a reduction of £1 5s. 5d. on present charges.

It is also anticipated that the fixed charge per annum will bear a reduction at an early date from £8 per kw. of maximum demand to £6 per kw., and that the diversity factor of two for general lighting may be equitably extended to three, which would halve the general lighting standing charge, and reduce the occasional lighting by 1s. 7d., and cooking by 5s., making a further reduction of £1 0s. 8d.

Taking the revised basis of charge, the following annual result is arrived at, viz:—

	£	s.	d.
Fixed Annual Charge ... ..	1	15	11
3,128 units at 0.5d. ... ..	6	10	4
Or 0.63d. per unit ... ..	8	4	3
Service Charges ... ..	2	7	6
Or 0.81d. per unit ... ..	10	11	9

at which price not only will the supply of energy compete successfully with gas, but the disability of competing with a rival power already in possession of the field will be removed.

### The Division of Costs Necessary in Determining Fixed and Running Charges.

In making an investigation of the varied costs which comprise the total cost of supply imposed upon an undertaking, it is necessary to dissect same under three distinct headings:—

First, the service cost, or the individual charge on the undertaking directly attributable to each consumer;

Secondly, the fixed cost, or the total sum necessary to carry on the undertaking, irrespective of the amount of energy supplied; and

Thirdly, the running cost, or the actual cost of supplying a unit of energy after making provision for service and fixed costs.

**Service Costs.**—It is now generally recognised that, in order to compete with other forms of power, light and heat it is necessary to wire premises completely, particularly when the consumer is a tenant only, and to install cooking and heating apparatus on hire at an initial expense to the undertaking. The author has assumed that the average "life" of the connection to mains, meter, wiring installation and cooking and heating apparatus is amply covered by an equal annual payment over ten years, plus 2½ per cent. equated interest. This is considered a safe provision, but, in order to cheapen the supply, it may be found practical to extend this period.

**Fixed Costs.**—All charges upon an undertaking of any description—other than service costs—which can be accurately or approximately stated at the commencement of each financial year are fixed costs. The sum of the charges thus stated, divided by the maximum demand made by the consumers as a whole, will produce a cost per kilowatt chargeable annually to each consumer, governed by the diversity factor of each class. The author suggests that the following charges can be allocated to fixed costs:—Interest and redemption, management charges, rent, rates, and taxes, inspection of mains, the wages payable to the running staff at the works and sub-stations (but not overtime and temporary labour, which are chargeable to running costs).

For the past year at Poplar, the service costs were 0.01d., the fixed costs 0.54d., and the running costs 0.303d. per unit sold.

The Paper would not be complete without reference to what might appear to be an important omission in connection with charges for a universal supply of electricity, viz., the prepayment system. The author has purposely refrained from introducing this phase of the supply because of the fact that little data are as yet available. It is proposed to go well ahead in Poplar very shortly, and, roughly, the outline of the policy is as follows:—Mains will be laid in every thoroughfare at the earliest opportunity, thus entirely eliminating gas from the streets. In connecting up, the first objective will be tenement buildings, which present the least initial outlay per head of the population. The consumers will be divided into three classes, viz., lighting only, lighting and hotplate, and lighting and cooker. Payment will be obtained through penny coin meters at a rate according to the demand of each class.

The cooking class will probably be charged at the inclusive rate of 1d. per unit (lower if possible), but an average monthly use of a given number of units must be registered or the meter will be changed to the hotplate class at, say, 2d. per unit, also with a minimum monthly use, from which transfers would be made to the lighting class at, say, 4d. per unit. This is a rough outline, which may be improved upon as experience is gained. Originally the Author favoured the idea of, and has had specially made, a differential meter which would change over after the insertion of a given number of pence at a higher rate than 0.5d. per unit, which would, with a certain monthly use at a high rate, return to the undertaking the fixed charge based on the cost of the installation, and then allow of the continued use to the end of the month at the running charge only. The great objection to such a system is that at the end of a month a consumer would probably be obtaining energy at the rate of 0.5d. per unit, but on the first and following days of the following month would have to pay 4d. or 2d. as the case might be. It was recognised that any such system would find ill favour with the working classes, as it would be impossible to explain the ethics governing such procedure. However, in order to preserve equity throughout it is practical to endorse on each consumer's card a number of units to be used each month, after which a return will be made to the consumer of the difference between 0.5d. and the rate at which energy is being paid for. Thus, if 250 units per month at 1d. per unit is considered a fair return for a cooking and lighting supply, a refund of 2s. 1d. would be made if 300 units were found to have been consumed.

### DISCUSSION.

Mr. C. H. WORDINGHAM (Admiralty) said that they were trying to sell a product and to get money for it, and all the juggling in the world would not prevent people having to pay for what was being sold to them. He did not agree with the remark that any available profits might be taken to provide special public improvements; this was quite inconsistent with the author's previous view that profits should not be taken to relieve rates. The proper thing to do was to put all profits back into the undertaking. Mr. Wordingham then indulged in some good-humoured chaff as to the author's announcement that the laws of expediency might govern private enterprise, but municipal enterprise was governed by the laws of equity, and quoted passages in the Paper relating to the arbitrary adjustment of diversity factors for the purposes of the tariff explained, to show that the author was not quite true to his principles. He did not say that expediency was wrong, but most makers of tariffs would, he thought, have to admit that they were based on expediency. He fully agreed with the author, however, that the rateable value system was an entirely inequitable and wrong basis, and he still firmly held to the old original Hopkinson system of charging. It did not so much matter whether the consumer understood it or not; what the consumer

did understand was his bill, and if he found by the Hopkinson system that he was charged less than by a flat rate it was all he wanted to know in the long run.

Mr. F. M. LOWE (Chief Electrical Engineer, Norwich) said that what might be equitable from the seller's point of view would not be always equitable from the buyer's point of view; it was no use having a system which produced the impression upon the consumer that he had been cheated. He took as an example a man who started with a 1-kw. radiator in his house, for which Mr. Bowden would charge him 8s. a year. This radiator was used first in one room and then in another, but in order to save himself the trouble of moving it about, the consumer put in another radiator. Mr. Bowden would want to charge him another 8s. a year, but the man would very reasonably object. With the high diversity factor obtained with a cooking load, current could be supplied at a flat rate, and in most cases at  $\frac{1}{4}$ d. The bulk of fixed standing charges were made up of interest and sinking fund on plant, which had cost far more than had to be paid now. It was possible to add plant nowadays at a very much lower rate, something between £3 and £4 per kilowatt, and it would be found that the running costs with a cooking load were about 0.3d. per unit. Mr. Bowden himself admitted this in the case of a power load. In competition with gas, electricity was in a much more favourable position with regard to lighting than heating and cooking, and they could therefore put all the high standing charges against lighting. If it were worked out it would be found in many towns that the rateable value did bear a very close relationship to the demand which a consumer would make for lighting his house. He took one of Mr. Bowden's examples and showed that practically the same charge would be arrived at under the rateable value system and in a very much simpler manner.

BAILIE W. B. SMITH (Glasgow) said he was in general agreement with the principles laid down in the Paper, and especially that the electricity department should not contribute to the rates. The man who had shut down his boiler plant and took electricity not only paid for his current, but under the present bad system actually paid a certain proportion of the rates of the man next door, who was working on the bad principle. Why should this manufacturer have to pay something to the Hospitals Rate when it was the man next door that was causing much of the ill-health in the town? He suggested that the convention should pass a resolution that in the I.M.E.A. Bill a clause should be inserted, prohibiting the use of electricity profits for the relief of rates. There was a precedent for this in the Glasgow Consolidated Bill in connection with the Glasgow Corporation gas undertaking, when the House of Lords struck out a clause enabling surpluses to be devoted to public services, on the ground that the clause had been in use for 46 years, but had never been put into force, and consequently could not have been needed.

ALDERMAN J. W. CROWTHER (Sheffield) gave some figures to show the tremendous field still unexploited for electric lighting purposes. On March 25th last there were in Sheffield 107,288 houses rated, and out of these 91,811 were under £15 per annum annual value; 6,827 at a rateable value of between £15 and £20 per annum; 3,299 were between £25 and £30 per annum; and the larger premises numbered 5,321. The rate books showed that of the 91,811 houses under £15 per annum only 10 per cent. took electricity; of the £20 to £25 houses, 35 per cent. were supplied; of the £25 to £30, 40 per cent. were supplied; and of the houses above that value, from 65 to 70 per cent. were supplied. It was stated in the Paper that shopkeepers were unfairly charged on the rateable value system, but in Sheffield they made concessions to shopkeepers, and offered current at 2d. instead of 4d., and so they would be put upon equal terms with the rateable value system.

Mr. H. RICHARDSON (Chief Electrical Engineer, Dundee) expressed the view that until the industry got hiring powers the cooking load must be regarded as a mere bagatelle. The public had been taught by the gas people to hire such things as cookers, and the electrical people would have to hire them in the same way. He had found in his own house that at  $\frac{1}{4}$ d. electricity competed well with gas at 2s. 2d., and he failed to see that it was necessary to go down to  $\frac{1}{4}$ d. per unit for heating and cooking to compete with gas at 2s. 6d. He agreed with the rateable value system, provided the circumstances were suitable, but in all towns this was not so. He had tried to apply it in Dundee, but had failed. If they tried to make themselves a little less exact in these commercial matters than they did in their engineering matters they would do better. He pleaded for simplicity, and did not agree with Mr. Wordingham that the consumer did not worry about how his bill was calculated so long as he could understand the amount.

Mr. A. S. BLACKMAN (Chief Electrical Engineer, Sunderland) said that the success which Mr. Bowden had achieved at Poplar was sufficient proof that there was nothing very far wrong with his tariffs, although in detail he might join issue with him upon several points. For instance, he thought Mr. Bowden was unnecessarily handicapping himself in sticking to his kilowatt charge, when he had ready to hand a very much more simple and more easily applied rateable value system. Mr. Bowden stated that he did not agree with another department of the Corporation assessing the standing charge for electricity consumers, but it was the electricity department which assessed

the percentage the consumer had to pay, and the fact that the electricity department merely made use of the scale of assessments already in existence could not be turned round and be used as an argument that the electricity department was being handed over to another department of the Corporation. It was perfectly painful to him to hear people talk about 1-kw. radiators. In Sunderland they had sent out 1-kw. radiators, and the result was nothing but dissatisfaction. They were now putting out nothing but 3 and 4 kw. radiators, and the result was absolute satisfaction. In Sunderland gas was cheap, but he found that at  $\frac{1}{4}$ d. he was doing a very large amount of heating indeed. He suggested that they should take a leaf out of the draper's book and deal in fractions of a penny. In Sunderland they fixed their lighting tariff at  $\frac{1}{4}$ d. for public houses, and he had now got every public house and hotel on his mains. There was no standardisation in the price of gas throughout the country, and he failed to see how we could expect to get standardisation in the charge for electricity throughout the country.

Alderman SINCLAIR (Swansea) said they could never obtain standardisation of price, although they might obtain some standardisation of method. He did not think the future of electric cooking would wait for any Parliamentary Bill. The time was bound to come when the electrical engineers and managers would have to give up all idea of peak load or maximum demand, and the fear of having insufficient copper in the ground, and sell any consumer current for any purpose he desired at a cheap rate.

Councillor A. H. DYKES (Beckenham) said that the poor man, with his two or three rooms, paid treble for his gas or oil lighting than those who used electricity. He gave some figures in support of this, and added that a penny placed in a penny-in-the-slot gas meter in most towns in England would not burn one gas lamp for a winter's evening. He mentioned that in Wimbledon Mr. Tomlinson Lee had connected to the main 5,000 lamps, every one of which was previously supplied by penny-in-the-slot gas meters. These represented 1,000 consumers, the increase in revenue was something over £1,000 a year, and by the end of the present year it would probably be nearly £2,000. He argued that it was unnecessary to put in a meter for this class of consumer. The few extra units which some consumers might use, he contended, would not necessitate more plant at the station, nor an increase in the size of the mains, nor additional supervision or wages. It simply meant (in A.C. stations at any rate) that these extra units would cost  $\frac{1}{4}$ d. a unit for fuel. What was the sense in putting in a meter, reading it, and maintaining it in order to ascertain whether a man with four lights was going to burn an extra 20 or 30 units per annum. Mr. Lee got over the difficulty of cost by running the service into the first house in a row, and looping through sometimes into as many as 20 houses from the one service. Although the system had only been in operation for some eighteen months, the number of lamps connected per service was 22 or 23, and it was increasing every month. This had been brought about by an arrangement with the Fixed Price Light Company, who dealt with the consumers direct on the basis of so much per lamp per week. At Wimbledon it was 3d. in the winter and 2d. in the summer, and the electricity undertaking had nothing whatever to do except to draw a cheque from the company each quarter.

Mr. A. NICHOLS MOORE (Chief Electrical Engineer, Newport, Mon.) said that if they once got into the minds of the members of the Councils that they were endeavouring by some means to overcome the local opposition of gas companies by cutting down prices, irrespective of the rates and the ratepayers, they would create an opposition which would be most injurious to them and their undertakings. He then proceeded to point out a number of discrepancies in the Paper, and he called attention to the fact that in the Poplar accounts the net profit from cooking and heating was only £600, and Mr. Bowden himself stated that it was due to his power load that he attributed his remarkable increase in revenue. Thus it was load factor and not diversity factor which was responsible for the improved results at Poplar, where 86 per cent. of the load had the very large power factor of 33 per cent.

Mr. J. W. BEAUCHAMP (Chief Electrical Engineer, West Ham) dealt first with Mr. Bowden's suggestion that the time would come when electricity would be supplied at a fixed charge without any secondary or running cost. This second charge, he contended, must be maintained, because no two consumers would use the same amount of electricity for the same kilowatts of demand. He disagreed with the rateable value system. There was no doubt, he said, that there was considerable relationship between the rateable value of domestic premises and the average bill for electric light, but he thought it was not right for another department to be able to alter the assessment of probably five-sixths of their consumers. Furthermore, he had been told that the Budget had foreshadowed to some acute person that there would be some different way of raising money as between the assessment of land and buildings, and this might knock such a tariff all to pieces. He suggested that the system might be used for a time merely as an internal indicator, but objected to declaring to the consumer that they based his charge on the assessment of his house. If a consumer's assessment was increased and his electric light bill was based on the assess-

ment, he would argue that he was not using any more light under his new assessment than under the old one. If he did not know the basis of his charge, he could not make this objection. On the other hand, he failed to see why the department should suffer because the assessment of a particular district went down.

Mr. F. S. GROGAN (British Electric Transformer Co.) said that Mr. Bowden's and the rateable value system had the same disadvantage, that with higher rated houses it was impossible to get the consumer to take on the domestic load, as his standing charge came out at too high a figure to start with. Mr. Bowden had brought out a very important point when he stated that the diversity factor of cooking would charge with different types of cookers. With a cooker which is very highly loaded in order to get quick initial heating of the oven, the diversity factor, with the maximum possible load on such a cooker, must be greater than on a cooker which would employ a lesser degree of loading for a long-continued period. He appreciated the value of slot meters for a cooking load, and the author's suggestion that a rebate should be made by the collector; this had been adopted successfully by the gas companies.

Mr. H. R. BURNETT (Chief Electrical Engineer, Barrow-in-Furness) said that in Barrow, out of 1,760 domestic consumers, 1,000 were of the artisan and labouring classes. Many of these had been supplied for about twelve years, and up to two years ago they were all charged through prepayment meters at 4½d. per unit. There had been many complaints, however, due to troubles with the meters and to the price paid, and he had instituted a system of charging at a fixed price per week, based roughly on the demands and also upon the rent, plus 1d. per unit. The effect had been to increase the consumption by 100 per cent., and there were now no complaints whatever. He thought it was unfortunate that many engineers had adopted as low a running charge as they had done. Mr. Vignoles in his Paper had worked out the running charge at 0.36d. with coal at 7s. 6d. per ton. Probably most engineers were paying nearly double that, and therefore a running charge of 0.5d. per unit would certainly not allow any margin for anybody paying 15s. per ton for coal. He could not help thinking that some engineers, either in their desire for notoriety or in order to qualify for membership of that very select body, known as the Point Fives, had allowed their judgment to be overweighed by that fact, and to fix prices which were not altogether justified by the costs.

Most of the members found time to pay brief visits to the places of historic interest at Stratford, and after lunch they returned to Birmingham by road, visiting Warwick Castle on the way. In the evening the Birmingham Entertainments Committee entertained them at an open-air fête in the Botanical Gardens, concluding with a splendid display of fireworks.

## THE POINT FIVE ASSOCIATION MEETING

WITH characteristic energy the "Point Fives" met on Thursday night, after the return from the fête at the Botanical Gardens, and the debate was opened by the Chairman, Mr. S. T. Allen (Chief Electrical Engineer, Wolverhampton), at the stroke of midnight.

He reminded the members that the principal objects of the Association are to encourage and develop the use of electricity for all possible domestic purposes. It might be said that so long as the Association was, as a whole, benefitting the undertakings of its members, they should be satisfied, but he did not hold this view. The results of the investigations of its members relating to cooking apparatus, for instance, were of great use, not only to the manufacturers, but to other undertakings, and it was distinctly to the advantage of the Association to publish their deliberations as widely as possible, and invite fair criticism both at their general meetings and elsewhere. That brought him to a point which they might discuss, viz.: were they aiding the manufacturers to decide what particular type of any piece of domestic apparatus was most suitable to the general body of users, and in what manner could they further the standardisation of apparatus. Standardisation must ultimately benefit themselves and the industry generally by cheapening the apparatus under consideration, and bringing it within the reach of a larger number of consumers. A standard could only be set up after a decision of a large majority of all interested parties that their specification conformed with the requirements which would benefit everyone concerned. This would also prevent the unnecessary changes in details which went so much towards hampering real progress. How often did we see, when something new and quite good had been designed to form the principal part of a piece of apparatus, that all the remainder was designed apparently with the idea of keeping it as unlike any existing and well-tried article as possible. It had been suggested that a central bureau might be established to test and report upon cooking, heating, and other domestic apparatus, but in his opinion the strongest bureau which could possibly

be established was already in existence, and had for its working committee the members of the Point Five Association. They were themselves handling a large proportion of such apparatus, and were closely in touch with a large number of householders and cooks who used it, and besides, the members and their staffs had the best opportunity of having practical tests made at home.

One of the things most impeding progress was the inability of a great number of authorities to hire out apparatus; immediately an undertaking was able to put into operation a suitable tariff, there arose a demand for cookers, heaters, &c., on hire. Those undertakings who possessed such powers had been able, with a suitable tariff, to increase their business enormously, and it seemed incredible that anybody, except those interested in the gas concerns, who already had such powers, could be opposed to any measure granting hiring powers to electricity supply authorities. He was of opinion that by far the greater majority of the "rank-and-file" of the electrical contractors were not opposed to any such measure.

In Wolverhampton they had full powers, and the point five tariff came into operation last autumn. During the first six months the number of private-house installations connected had been three times as many as the number during the same period during the year previously, and they had supplied on hire just 500 kw. of heating and cooking apparatus. Through the kindness of the other members, he had been able to ascertain that, since the point five tariffs had been in vogue, connections for about 10,000 kw. had been made, and about 7,000 kw. of cooking and heating apparatus had been connected up in private houses. Obviously, without the hiring powers, the greater portion of the 7,000 kw. would never have been connected at all—much to the loss of the consumers, the manufacturers, the supply undertakings, and to the wiring contractors, who carried out more than three-quarters of the necessary wiring work.

In the concluding part of his address, Mr. Allen referred to the electric vehicle question. This brought up a tariff question which would probably have to be considered by several members before long, viz.: How should electric car battery supply be charged to those domestic consumers now enjoying the point five tariff? Owners of private electric cars would not be content to use the central charging stations. Battery vehicles of the present types would be restricted a good deal, so far as private vehicle users are concerned, to doctors and such persons, who would use the vehicle purely for local travelling, so that the charging supply should be a regular one, and a good one so far as revenue was concerned, provided that the tariff was correct. He did not think that domestic consumers already enjoying the point five tariff could be definitely restricted in the times they should take such charging supply, and a two-rate tariff (on flat rates) would not be sound. He saw no reason, however, why such a demand could not be treated separately on the differential system of charging with the units used charged at a halfpenny per unit. The fixed amount per annum could not in this case be so easily determined as that due to a lighting supply, for instance.

Mr. T. ROLES (Bradford) said that he was considering putting shops on the point five tariff, but the difficulty was with the fixed charge, as in this case the rateable value system would not be suitable. [Mr. Bowden: Hear, hear.] He referred to the Bradford Exhibition, an announcement with regard to which appeared in our columns last week. This had been recognised by the B.E.A.M.A., to whose requirements they had given way in some respects, but these had been more or less reasonable, rather more than less. He agreed that a standard cooker was desirable. So far at Bradford there had not been much cooking, and he was looking to the Marylebone experiments and hoping to introduce a hire system soon. He complained that the Point Fives were not taken sufficiently seriously by the I.M.E.A., and thought that they should be better represented on the Council.

Mr. W. A. VIGNOLES (Grimsby), who is not yet a member of the Point Fives, referred to his Paper (published last week), which showed that the point five tariff could be applicable in his town. He presumed, however, from the Chairman's address, that a second charge of slightly over a ½d.—say ¾d.—would also bring eligibility to the Point Five Association. He agreed that the Association should be better represented on the Council of the I.M.E.A.

Mr. A. H. SEABROOK (St. Marylebone) said that in his district the comparatively small motor load had now all been catered for, and cooking had become regular routine work. He was, in fact, now discontinuing some of the records of faults, &c. On his hiring system, he found that, after allowing for maintenance, &c., a small margin was left for depreciation. His recent experience with water heating with improved thermostats now obtainable showed that electricity at ½d. worked out at a lower cost than gas at 2s. 6d. These electric water heaters with thermostats were now being used in public conveniences in Marylebone. A new application of electric heating such as this would entirely upset Mr. Bowden's proposed tariff. One of the most urgent things to be dealt with now was the trouble with "flex"; he suggested that something like cab-type sheathed cable should be used, but with a nice-looking braiding. Another was the screw lamp-holder, which he thought they should endeavour to get the Engineering Standards Committee to standardise, and he hoped that this type of holder would be retained for half-watt

lamps. He did not think that there would be any difficulty in using the rateable value system for electrical vehicles, as the houses with garages were already rated higher on that account. As to the rateable value system generally, he had kept careful records for twelve months, and found that the fixed charge on that basis agreed very well with his previous assessments.

Mr. J. H. BOWDEN (Poplar) said that he was hoping to hold a joint electrical exhibition with Stepney, Shoreditch, and Hackney in the near future. He suggested that a cooker with a hot-plate which showed red-hot would be much approved.

Mr. J. CHRISTIE (Brighton), who is not a member of the Point Fives, said that if he introduced the price of 0.5d. per unit for cooking, the tramways would ask for 0.5d. also. At Brighton he supplied for the tramways and other power purposes four or five million units at 1d. less 10 per cent., and did not want to lose practically half this revenue. He mentioned also that he was applying for a loan for heating and cooking apparatus, on the basis of a ten-years' life, and was waiting to see how the L.G.B. received the proposal.

Mr. S. E. FEDDEN (Sheffield) said that the rateable value system was only intended for small consumers. He was extending heating to small shops, offering a discount of 50 per cent. off the standard heating and cooking rates on a guarantee of  $4\frac{1}{2}$  hours user per day; the price could thus be calculated in advance. He hires out cookers costing £8 or £9 at 4s. 6d. per quarter, as he feels that the cost of these will go down in the near future, but does not hire out heating apparatus, as the demand for them is already greater than he can get deliveries for. He believed in high ratings for radiators, and supplied 2, 3, and 4 kw. fires for installing alongside gas fires as an experiment; the experiment was always successful. Several restaurants were being supplied at  $\frac{1}{2}$ d. a unit plus a fixed charge, after their proprietors had inspected successful installations in London.

Mr. W. H. COOKE (Luton) said that it was not the object of the Point Fives to discuss whether the rateable value system should be adopted or not. When the system answered, it was pure chance that the assessment of the other department had happened to agree with the charge that should be made by the electricity department. He himself used a flat rate of 0.5d. per unit. In dealing with inquiries for industrial purposes, he had sometimes been able to quote as low as 0.35d.

The discussion was carried on by Mr. NICHOLS MOORE (Newport, Mon.), Dr. H. GERVIS (Brighton), Mr. A. S. BLACKMAN (Sunderland), and Mr. F. W. PURSE (Carlisle).

Mr. GOGAN (British Electric Transformer Co.) spoke in strong opposition to the use of 400 or 500 volts on cookers—by balancing the two parts of a cooker on the three-wire system—which had been authorised by the Board of Trade at Marylebone and Birmingham. He argued that a switchboard attendant might break the station earth connection, and so endanger the life of a cook working on an electric cooker which had developed a fault.

The meeting terminated shortly after 2 a.m.

## ANNUAL GENERAL MEETING

The annual general meeting was held in Birmingham on Friday.

As a result of the alteration in the Articles of Association sanctioned at the annual meeting last year, the election of Council and officers is now carried out exactly as by the Institution of Electrical Engineers. Accordingly a list of the Council's nominations had been circulated previously to the meeting, but no further nominations were received. As the result of the ballot, the Council will be constituted as follows for the ensuing year:—

**President:** \*H. Richardson (Dundee).

**Vice-Presidents:** A. C. Cramb (Croydon) and \*F. M. Long (Norwich).

**Past Presidents:** J. Christie (Brighton), G. Wilkinson (Harrrogate), and R. A. Chattock (Birmingham).

**Other Members of Council:** A. H. Seabrook (Marylebone), S. J. Watson (Bury), F. Ayton (Ipswich), T. Roles (Bradford), S. E. Fedden (Sheffield), W. Wyld (Hampstead), \*W. A. Vignoles (Grimsby), \*J. W. Beauchamp (West Ham), \*A. S. Blackman (Sunderland), Councillor Gibson (Wolverhampton), Alderman Sinclair (Swansea), Alderman J. P. Smith (Barrow-in-Furness), Councillor Ellaway (Birmingham), \*Alderman Crowther (Sheffield), \*Councillor W. B. Smith (Glasgow).

The names of members elected to fill the vacancies are marked with an asterisk.

A portrait of the new President appears opposite.

Some discussion took place as to the form of the ballot paper, which stated that the number of names left "must not exceed or be less" than the number required for the several offices. One or two members took the view that there should be the right to vote for a less number than the required number; in other words, that "plumping" should be allowed. It was pointed out that the Articles of Association did not permit of this, and a subsequent resolution by Alderman Foster (Portsmouth), seconded by Mr. F. W. Purse (Chief Electrical Engineer, Carlisle), that future ballot papers should be altered

in this respect, although receiving a fair amount of support, was easily defeated.

The place of meeting next year was left for final choice with

H. RICHARDSON.  
(President of the I.M.E.A.)

the Council, although Bailie Nairn, of Dundee, said the Corporation would be most happy to give the Association a hearty welcome to the city.

## Annual Report.

The annual report, which is abstracted below, was next presented. Much of the information has already been reported in our columns, through the courtesy of the Association, and is not now repeated.

**Membership.**—The membership of the Association now stands at 379:

Committees (Members) ... ..	165
Chief Electrical Engineers (Members) ... ..	175
Honorary Members ... ..	6
Chief Assistants (Associate Members) ... ..	4
Assistants (Associates) ... ..	29

379

There is a decrease of seven on last year's total, chiefly among the Associates.

**Standardisation of Metal Filament Lamps.**—The Association's representatives on the Lamp Standards Committee of the Engineering Standards Committee (Messrs. Fedden and Wilkinson), in conformity with a unanimous resolution of the Council, urged the adoption of watt marking only. They found themselves in direct antagonism with representatives of the War Office, the Admiralty, the Post Office, and Public Works, all of whom were tied down to vote under the direction of their respective departments, though, as a matter of fact, they were personally in sympathy with the views of the I.M.E.A. The Standards Committee, by the majority of the votes from these officials, decided to adopt the standard of marking both the candle-power and watts on lamps. The I.M.E.A. strongly objected to this, and urged the Tungsten Lamp Association to adhere to the resolution already adopted by them in regard to watt marking only. The Tungsten Lamp Association in reply expressed their hearty approval in support of the marking of all lamps with watt rating only. The only exceptions made by members of the Association were where Government Departments made specific requests for candle-power markings.

It is not likely that an acceptable specification will be issued by the Standards Committee unless the contemplated rearrangement of the Standards Committee should result in considerable change in its constitution.

**Electric Lighting Bill.**—The Council has spared no efforts to press forward this matter, and desires to acknowledge the work done and assistance rendered by Mr. Hugo Hirst and the late Mr. A. Bruce Anderson, Chairman of the B.E.A.M.A. A circular letter was sent to all members of the Association with regard to securing promises to ballot from the various Members of Parliament, but no place was secured which could be of practical use. A new clause for the exemption of fittings, &c., let on hire by contractors has been inserted, and the powers originally sought under Clause 1 (powers to provide electrical fitting) has been amended, and the Bill in its present form has the support of the British Electrical and Allied Manufacturers, and it is believed of all other interested parties except the Electrical Contractors' Association, who have declined to accept

the proposed amendments and have also signified their refusal to have the matter submitted to arbitration. [An abstract of the Bill appeared in *ELECTRICAL ENGINEERING* of March 5th, 1914, p. 127.]

**Model General Conditions.**—The report states the position of the Association in this matter, which was mentioned in the President's address, published last week.

**Gas Companies and Electricity.**—A large number of gas companies have sought powers to carry out the generation and distribution of electricity. Opposition has been brought to bear in several cases, and promoters have withdrawn the clauses to which exception has been taken.

**Industrial Committee.**—The Institution of Electrical Engineers having disbanded the Industrial Committee, the Council have considered the desirability of the formation of an influential body representative of all sections and departments of the electrical industry, competent to deal with all matters of grave importance to the industry. It was agreed that the proposal be approved in principle, and that preliminary arrangements be entered upon.

**Engineers' Salaries.**—At the annual general meeting last year Mr. Burnett, of Barrow, asked the Council to consider the question of the salaries paid to central station Engineers and their assistants, with a view to bringing pressure to bear upon municipalities to improve their position. The matter was carefully considered in all its bearings, and while in agreement with the suggestion in principle, the Council was unable to take further action in the direction indicated.

**Travelling Studentship.**—There have been no entries for the Travelling Studentship during the past three years, and the Council's communications to the Associates regarding the reasons for the lack of interest in the matter, and inviting observations and suggestions, did not elicit any helpful response.

**Standardisation of Electrical Apparatus.**—A Sub-Committee, consisting of Messrs. Cramb, Wilkinson, Fedden, and Seabrook, has been appointed to deal with the standardisation of electrical accessories, including cooking appliances. The Engineering Standards Committee have invited the appointment of two I.M.E.A. representatives on their Electrical Plant Accessories Sub-Committee. Mr. Cramb and Mr. Seabrook have been so appointed, Mr. Wilmshurst, the former representative, having resigned. It is considered desirable that the I.M.E.A. should be represented upon all Sub-Committees of the Standards Committee on Electrical Engineering, and the Engineering Standards Committee have been approached upon this matter.

**Yorkshire Electric Power Co.'s Bill.**—The Council, having first ascertained that all Local Authorities affected by the above Bill were taking action, resolved as follows:—"Whereas the Association note with concern the attempt of the Yorkshire Electric Power Co., in its Bill, to appropriate all districts within its area which do not already form part of the area of supply of an authorised distributor; also in view of the fact that such powers would seriously interfere with the development of municipal areas, and would in all probability entail a payment of compensation for goodwill in the event of an extension of borough boundaries or municipal lighting areas, the Council note with satisfaction that a petition is to be presented by the non-County Boroughs of Batley, Brighouse, Doncaster, Keighley, Morley, Ossett, and Todmorden, and assures the various authorities of the moral support of the Petition."

**N.A.L.G.O. Delegate's Report.**—The Council of the National Association of Local Government Officers held a very successful meeting at Bristol on March 14th. A superannuation scheme has been prepared, about two hundred members of Parliament supported the principle, and the Chancellor of the Exchequer is being asked to receive a deputation from the Association, when the possibility of a grant from the Government towards the cost of the scheme will probably be raised. The establishing of a Provident Section to commence with a deposit scheme for sickness benefits, and a scheme for death benefits, was also discussed, and the recommendation carried. The I.M.E.A. Council is represented on the National Council of the N.A.L.G.O. by two members, Mr. J. E. Edgcome and Mr. Wyld, but Mr. Edgcome was unable to attend the meeting through illness.

## DISCUSSION.

### The I.M.E.A. Bill.

The HON. SECRETARY (Mr. H. Faraday Proctor), in answer to a question by Mr. Hoadley (Maidstone), said that the exact position of this Bill from the Parliamentary point of view was very much the same as it was at the last Annual Convention. The Association had circularised all the municipalities, asking them to get their Members of Parliament to do what they could for the Bill and to ballot for a place, but they had not been able to obtain more than two or three promises up to the date of the taking of the ballot. If the members of the Association could not get their Members of Parliament to do something in the matter, it would be impossible for the Association to get the Bill through on present lines. The Association had the sympathy and the active interest and support of everybody interested in this matter, with the exception of the Electrical Contractors' Association. They had the support of the technical Press, with the exception of *Electrical Industries*. They also had the support of the B.E.A.M.A. He felt that if a large

number of members could join together and promote a Bill for their own undertakings, instead of relying entirely on the I.M.E.A. Bill, they would be successful in getting the powers they wanted. The difficulty was not in getting the Bill through the House itself as getting it before the House. They had the support of Lord Amthill, who had promised to give his active support in the House of Lords. Lord Amthill had told him that he was sure the matter was misunderstood when it was before Parliament previously, and now he (Mr. Proctor) really did not fear the House of Lords any more than he feared the House of Commons.

Mr. W. C. P. TAPPER (Stepney) asked if it would be possible to initiate the Bill in the House of Lords instead of in the House of Commons.

The HON. SECRETARY replied that the Hon. Solicitor said, practically speaking, it would not be possible.

Mr. C. TURNBULL (Tynemouth) asked if there was any precedent for a combined Bill of this sort.

The HON. SOLICITOR said there were precedents among the gas companies who had promoted Bills jointly for removing the restrictions upon the right to send sulphur fumes into houses and public streets, and they had been successful in getting these restrictions removed.

Mr. C. F. McINNES (Gravesend) proposed that the Council should take steps to ascertain which municipalities would join in promoting a combined private Bill.

This was put to the meeting in the form of a resolution, seconded, and carried.

Mr. R. H. CAMPION (Dewsbury) said that if this was done it would assist many authorities in the same position as his own. The Dewsbury Corporation were going for Parliamentary powers in an "omnibus" Bill, and were inserting these clauses. The Town Clerk had told him, however, that these clauses would be dropped if they were opposed, and therefore if a combined Bill could be promoted it would be of great assistance to him.

### Model General Conditions of Tender.

The HONORARY SECRETARY stated, in reply to Mr. Brydges (Eastbourne), that the views of the I.M.E.A. Council were not very divergent from those of the Institution of Electrical Engineers. He reminded the meeting, however, that twelve months ago the members did not agree with certain recommendations made by the Council of the I.M.E.A., and it was decided that nothing further should be done until the Association of Municipal Corporations had made a move in the matter, and that no communication be made with the B.E.A.M.A. meanwhile. Although the Association of Municipal Corporations was communicated with twelve months ago, he had only received on the previous morning a communication from the legal committee of that body, and this had still to be submitted to their full Council. He had received a communication from the B.E.A.M.A. stating that they were proposing to adopt the conditions as issued by the Institution of Electrical Engineers for a period of one year in respect of municipal contracts in order to see how they worked. The views of the I.M.E.A. were asked upon this matter, but the Council had not been able to deliberate upon it because the members had tied their hands by the resolution passed twelve months ago; he did not think the Council could take any active steps until their hands were untied. He thought it could only be left to municipalities to deal with the manufacturers as points arose.

### I.M.E.A. Conditions for Supply of Electricity.

A draft of proposed conditions had been attached to the Report.

Mr. J. A. BELL (Aberdeen) drew attention to the question of fire insurance of the supply authorities' apparatus upon a consumer's premises. In a recent case he was unable to recover because negligence could not be proved against the consumer.

The PRESIDENT said the point would be considered before the conditions were finally issued.

Mr. A. G. COOPER (Colne) said the same thing applied to apparatus on hire.

The PRESIDENT said there was always a special agreement with the consumer for the hire of apparatus, and that should include special provision against fire.

Mr. W. C. P. TAPPER (Stepney) said he had got over this difficulty by taking out a special policy at Lloyd's to cover any apparatus on hire, motors, service lines, &c., and did not worry the consumer about it at all. The premium was 2s. 6d. per cent.

Mr. H. S. ELLIS (South Shields) thought this matter should be looked after by the department, as consumers objected to be worried with these matters.

The report, including accounts, were then put to the meeting and carried.

### The late Mr. A. B. Anderson.

On the motion of the President, the following resolution was passed, the members standing:—"The members of the I.M.E.A., in their annual meeting assembled, are desirous of expressing to the widow and family of the late A. Bruce Anderson, Esq., their sincere sympathy and regret at the deplorable loss sustained owing to his death on the occasion of the foundering of the *Empress of Ireland*, also to sympathise with the B.E.A.M.A. in the loss of such an energetic and valuable Chairman."

### The Industrial Committee of the I.E.E.

Mr. A. H. SEABROOK (Marylebone) moved the following resolution: "That this Association regards with dissatisfaction and regret the dissolution of the Industrial Committee of the Institution of Electrical Engineers. They consider that it is within the province of the Council of that Institution, and urge that steps be taken to watch over the industrial and commercial, as well as the scientific and technical interests of the membership."

Mr. A. C. CRAMB (Croydon) seconded.

After a short discussion, it was seen that the general feeling of the meeting was that it would be a wrong policy also for one association to censure another, although several members sympathised with the object of the resolution, and Mr. Seabrook therefore withdrew it.

### The Development Committee.

Mr. W. A. VIGNOLES (Grimsby) moved: "That a Special Committee be formed of members of this Association, not necessarily members of the Council, to deal with any matters that may tend to encourage the use of electricity from the public supply mains, and that this Association shall invite other associations and persons who may assist in furthering the object for which the Committee is formed to join such Committee." It had been suggested, continued Mr. Vignoles, that a Committee should be formed to replace the defunct Industrial Committee, but this he regarded as too large a task for the Association to tackle. An association had been formed some time ago called the "Association for the Protection of Electrical Interests." It met a few times, but apparently did not find anything to protect, and finally abdicated. After that the Industrial Committee of the Institution of Electrical Engineers, as they had heard was formed, and met on a number of occasions, but that finally committed suicide. The reasons for this he thought was that these committees were not promoted by the right people, or did not get the right members upon them, or there was a clashing of interests. This would not be the case with the new committee, because the interests of all the members of the I.M.E.A. were the promotion of the use of electricity. He proposed that it should be left to the Council to select the Committee.

Mr. T. ROLES (Bradford) seconded. Some such action as this, he said, was necessary in view of the activities of the British Commercial Gas Association, and the class of man required upon it was represented by Mr. Vignoles himself.

Alderman J. P. SMITH (Barrow-in-Furness) suggested that it would be wiser to take some particular subject and appoint a committee to go into that. The Electric Vehicle Committee was an example of the advantage of that policy; to tackle the whole question of publicity throughout the electrical industry was a very big subject, and he would like to put forward a suggestion which he had heard made on the previous day that a committee consisting of three or four members of the Council and others directly interested in cooking should be formed to deal with the matter specially. A round table conference between that committee and manufacturers of apparatus to discuss the pros and cons would do an immense amount of good. There might be other things which could be tackled in the same way later on.

Mr. F. AYTON (Ipswich) expressed his entire sympathy with the proposal made by Mr. Vignoles.

Mr. J. E. EDGECOME (Kingston) said that he supported the proposed committee in whatever form it was appointed. The suggestion that round table conferences between manufacturers and supply authorities would bring good results was emphasised by what had been accomplished by the Diesel Engine Users' Association, where they adopted the policy of discussing a particular point at each meeting with the manufacturers of a particular part of the apparatus. For instance, at one meeting they had discussed compressors, and the representative of Messrs. Reavell, who made these for a large number of Diesel engines, had given a great deal of useful information to the users of Diesel engines. That Association also was not confined to central station engineers, but any user of a Diesel engine in whatever form was eligible for membership.

Mr. W. H. COOKE (Luton) also expressed his support of Mr. Vignoles.

Mr. A. H. SEABROOK did not think it was worth while discussing details. The great point was to support Mr. Vignoles' proposal, and to elect the committee.

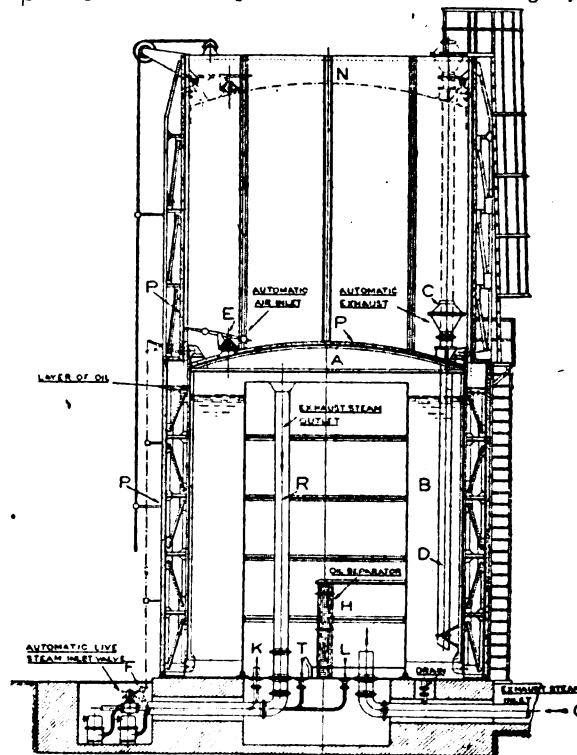

The resolution was then put to the meeting and carried unanimously.

Votes of thanks to the President, the various municipalities, and manufacturers who had entertained the Association during the Convention, and to the honorary officers, were then passed, and the proceedings closed.

The visit to the Birmingham Electricity Works on Friday afternoon was well attended, as was also the visit to Worcester on Saturday; a special train had to be engaged for the Worcester visit. Descriptions of these works appeared in our issue of June 11th.

## THE BALCKE-HARLE EXHAUST STEAM ACCUMULATOR

A TYPE of exhaust steam accumulator working in a similar manner to a gasometer, which is in use to a considerable extent on the Continent, is being introduced to this country by Balcke & Co., Ltd. (Broadway Court, Westminster, S.W.). The main point of difference between its working and that of the Rateau accumulator for dealing with an intermittent supply of steam for exhaust steam turbines is that while in the latter the steam is condensed, and re-evaporated when required by the stored heat, in the Balcke accumulator the steam is stored as steam and treated like a gas. The construction of the apparatus will be understood from the figure. The main bell, A, of rivetted steel plate floats in a water tank, B, and carries certain valves, including an automatic exhaust valve, C, consisting of a silencer and a pipe, D, which is completely sealed by the water in the annular space so long as the bell is below its highest predetermined position. If the bell rises higher, the

SECTION OF EXHAUST STEAM ACCUMULATOR.

pipe is uncovered, and the steam can escape. There is also an air inlet valve, E, which is mechanically opened when the bell reaches its lowest position, but will also open automatically if at any time the pressure in the bell sinks below the permissible value. As it is not desirable that air should be admitted very often, a live steam admission valve F is provided which is also worked mechanically and opens before the air inlet valve. The exhaust steam reaches the accumulator through the pipe G and the oil separator H, and passes to the turbine through the pipe R. Condensed water is removed through T and L and drains the separator. The whole outer shell is well lagged, and the water in which the bell floats is covered with oil to reduce evaporation and heat loss. The condensation losses are extremely small, and very little back pressure is produced. In the case of mixed-pressure turbines it is possible to control the governing by the movement of the bell.

**Electrification Produced by Dust Clouds.**—A Paper read recently before the Royal Society by Mr. W. A. D. Rudge on electrification produced during the raising of a cloud of dust, deals with a phenomenon which may prove of importance in connection with stone dusting and the coal-dust question generally. Mr. Rudge finds that the raising of a cloud of dust is accompanied by the production of large charges of electricity. Some of the dust particles have positive charges, and others negative. Either one set of charged particles settles rapidly, leaving the other set in the air, or else a charge is given to the air itself. The experiments do not show which of these views is correct. The charge is retained by the air for some considerable time. The sign of the charge remaining in the air depends upon the nature of the material used. "Acidic" bodies, such as finely-divided silica or molybdenic acid, give to the air a negative charge, whilst "basic" bodies, such as lead oxide, or organic dusts, such as flour or coal, give a positive charge. The friction between particles of similar material apparently produces sufficient electrification to account for the charges observed.

## THE FERRANTI-WATERS FEEDER PROTECTIVE SYSTEM

WE describe below a system of feeder protection for isolating faulty feeders, which has been patented by Mr. Eric G. Waters, of Messrs. Ferranti, Ltd., and is being introduced by that firm. It is already in use to a limited extent in Marylebone, and is, we understand about to be installed in some other places.

The simplest form of gear is for the case in which two sub-stations, each independently fed from the generating station, are connected by duplicate feeders. This is shown in Fig. 1, in which, to avoid confusion of lines, the three-phase cables are shown as single lines only. Immediately below the trifurcating box on each feeder is placed a ring-type current transformer, *CT*, which is simply threaded over the cable. Each has two secondary windings, *A* and *B*, which are connected together, as shown, through the coils of a dynamometer pattern relay; the secondaries *A* are connected

Fig. 1.

in series, and the secondaries *B* are cross-connected. The relay is a double-acting one, i.e., it can operate in two directions, thereby completing the trip coil circuits, *TC*, of an oil-switch in one or other of the feeders.

A ring-type transformer placed around a three-phase cable is unaffected by the passage of currents in the three cores in the ordinary course, whether the phases are balanced or not, since their vector sum is always zero. If, however, a fault to earth occurs, the current transformer becomes magnetised, inducing an E.M.F. in the secondary windings.

If the fault occurs on a part of the system beyond the duplicate feeder, the out-of-balance fault current divides equally between the two feeders in parallel. The E.M.F.'s induced in the secondaries *B* will assist one another, and current will flow through the coil of the relay connected to them; but, in the case of secondaries *A*, the induced E.M.F.'s will be equal and opposite, and no current will flow through that coil of the relay. Consequently the relay will not operate, and the feeders will not be cut off, which is as should be.

If the fault occurs on one of the duplicate feeders shown in the diagram, however, say the top one, this will carry a greater proportion of the fault current, and its secondary *A* will overcome the secondary *A* on the other feeder, causing a current to circulate in a certain direction through one coil of the relay. Current will also flow through the other coil in a certain definite sense. If the fault occurs on the bottom feeder, the current in the secondaries *A* will be reversed, but the current in the secondaries *B* remains in the same direction. This means that the relay will operate in one or other direction under these two conditions, thus cutting out the feeder which has developed the fault. In addition to the connections mentioned, there is a switch in the circuit of each of the *A* secondaries, which is mechanically coupled to the main switch. As soon as the main switch is operated this opens the circuit of these, and prevents the relay from acting, due to the currents which would otherwise be induced in the secondary circuits by current flowing to the fault through the healthy feeder and the sub-station, due to possible slow action of the oil-switch at the other end.

This applies to the supply end of the duplicate feeder. If the duplicate feeder is part of a ring, or connects two generating stations, the gear, as described above, is duplicated at the sub-station end. A third feeder, providing an alternative path to the sub-station, also satisfies this condition.

If, however, there is no alternative supply to the sub-station beyond the duplicate feeder, the protective gear at the sub-station end is modified as shown in Fig. 2. In this case current transformers are placed in each phase of each feeder. (To simplify the diagram one only is shown.) The secondaries of the two transformers in similar phases are connected to each other through two current coils of a special three-coil relay. The third coil of this relay is connected

to the secondary of a potential transformer, *P.T.* Details of this relay are shown diagrammatically in Fig. 8. The voltage coil is fixed, and the two current coils are pivoted on a counterbalanced arm and disposed one at each side of the voltage coil.

Fig. 2.

Normally the phase currents to the sub-station are equal and in the same direction. This means that the secondary E.M.F.'s of each pair of current transformers are equal and opposite, so that no current flows through the two current coils of the relay. If, now, a fault occurs on the top feeder, the current in this feeder is reversed. The secondaries now

Fig. 3.

assist each other, and a strong current flows through both current coils. The coils are so wound and connected that in these circumstances they repel each other, but being on a dead centre, no motion takes place until a slight displacement of one coil is effected by the action of the voltage coil. It will be seen that one current coil will be forced against its stop, and the other will be forced away. As soon as this displacement has been effected, the motion of the moving coil is maintained by the repelling action, so that it is immaterial if the value of the voltage falls even to zero. Or to explain this in another form, the two current coils are repelling each other under the fault condition, and there is no certainty which will be forced away from its stop. This is a form of unstable equilibrium, and all that the voltage coil is called upon to do is to give one or other of the current coils a very slight impulse.

If the fault is on the bottom feeder the results are reversed, the other current coil being the one to be moved. Thus the oil-switch in one or other of the feeders is operated through the medium of its trip coil. The faulty cable is thus cut out at both ends, and the healthy feeder is left to carry the load.

A very interesting and useful feature of the case shown in Fig. 1 is that tappings may be teed off the feeders in parallel without affecting its operation.

**The Royal Society Conversazione.**—Amongst the many interesting exhibits at the Royal Society Conversazione, which was held at Burlington House on Tuesday, June 16th, was an apparatus invented by Mr. W. M. Mordey for obtaining an oscillatory motion by electrical means without the use of a make and break. This is accomplished in a very simple manner. A small single-phase induction motor with squirrel cage rotor has two spiral springs attached to one end of the shaft. When an A.C. voltage is applied to the stator terminals, and the shaft is given an initial twist, it will continue to oscillate until the current is switched off. The British Thomson-Houston Co. had on view an X-ray tube invented by Dr. W. D. Coolidge, of Schenectady. The cathode consists of a tungsten spiral, and the anticathode is also of tungsten. A very high vacuum exists inside the tube which rectifies its own current and can therefore be worked from either direct or alternating supply. Another apparatus shown by Lt.-Col. G. O. Squier was designed to enable the ordinary telephone transmission wires to be utilised as antennae for radio-telegraphy, without any interference of the ordinary working occurring. Dr. E. E. Fournier D'Albe gave a demonstration of his Optophone, to which a separate article in this issue is devoted.

**Venner Signs.**—In the Chancery Division on June 12th, before Mr. Justice Astbury, Mr. F. Russell, K.C., on behalf of Venner Signs, Ltd., had a motion for an injunction to restrain the Stella Signs, Ltd., from selling signs alleged to be an infringement of the Venner patents. He mentioned, however, that having received all the affidavits in the matter, there was such a conflict of opinion as to the facts, that he did not feel justified in asking for an interim injunction. The date of the trial has not been fixed.

## THE NATIONAL PHYSICAL LABORATORY

ON Friday last, on the occasion of the Annual Meeting of the General Board of the National Physical Laboratory at Teddington, the opportunity was given to a large invited party to make an inspection of the Laboratory and its equipment. The guests were received by Sir William Crookes, P.R.S. (Chairman of the Board), Lord Rayleigh (Chairman of the Executive Committee, Sir A. B. Kempe, and Dr. R. T. Glazebrook (Director of the Laboratory).

There are no very striking changes in the buildings or equipment since last year, when, it will be remembered, Mr. Balfour opened extensive new premises, but a detailed inspection revealed an immense amount of progress in matters of detail in the individual departments, immense activity in all the branches, and a continuous broadening in the range of work covered. Among new branches of work may be mentioned the recently introduced radium department, where the British radium standard is kept. It is regrettable that in the annual report it has been found necessary to draw attention to the large financial liability now incurred by the Royal Society in the management of the Laboratory. The income during the past year was nearly £44,000, and the greater part of this sum is received as payment for work done, the Government grant-in-aid for general purposes being only £7,000 a year. The technical societies and institutions represented on the General Board have urged that while it is desirable the control of the Laboratory should remain in the hands of the Royal Society, it is necessary for its proper development that increased Government support should be given, and that steps should be taken to free the Royal Society from the serious financial difficulties that would arise in the event of a falling off in any year in the receipts for work done, and from the necessity of finding the working capital. The matter is now under consideration by the Royal Society with a view to the Government being approached.

Turning now to the electric work carried on at the Laboratory, which is the portion of most interest to our readers, from some points of view the greatest importance attaches to the completion of the determinations of the ohm by the new Lorenz apparatus by Mr. F. E. Smith, who has achieved the hitherto unapproached accuracy of 4 parts in 100,000, and now gives the international ohm as  $1.00052 \times 10^9$  C.G.S. units. Other important work in the electricity section of the physics department has been the extensive international and other comparisons of standard resistances, and further experiments with the standard current weigher. Interest also attaches to the magnetometer equipment, which has been prepared to check that the magnitude of the magnetic disturbances caused by the forthcoming electric working of the neighbouring lines of the L. & S.W. Ry. do not exceed the allowable value. In the section dealing with general electrical measurements, Mr. Campbell has continued during the year his work on the measurement of inductance and capacity at the high frequencies employed in wireless telegraphy, and has evolved satisfactory methods of measuring these over a wide range. He has also been successful in devising means for measuring the power conveyed by high frequency currents. Reference may be made, too, to the researches on magnetisation under large magnetising forces, and special tests of the permeability of the iron wire and strip used for lapping telephone cables to increase their inductance. In addition to all the experimental work, 259 tests have been made in the department during the year.

The electrotechnics department has been working in two senses at very high pressure. The tests made total 3,828 for the year, of which an important part was the testing of apparatus at pressures up to 20,000 volts by the electrostatic wattmeter under Mr. Rayner. A very useful piece of apparatus has been added to the equipment in a 20,000 change-over switch, actuated by cords from the instrument enclosure, so that no time is lost in making three-phase power measurements by the "two wattmeter" method on a single instrument. All the apparatus connected with the standard electrostatic wattmeter is now very conveniently arranged, and this, together with the extraordinary dead beatness and absence of zero creep of the instrument itself render it possible to use this equipment for a very large amount of practical testing work. A good deal of special testing of ebonite has been done for the Admiralty, and other work has included heating tests of field coils and experiments in connection with the E.S.C. specification for supply meters. There has also been a considerable increase in the direct current and resistance measurements under Mr. Melsom, entailing additions to and improvements in apparatus. The research work has included investigations of the heating of wires and cables for the Institution of Electrical Engineers, the work on the heating of buried cables being particularly interesting. Tests of the conductivity of steel rails have also been carried out for the Engineering Standards Committee.

In the photometric division, the inter-comparison of the high efficiency standards of the principal standardising laboratories has been concluded with gratifying results, and other important researches have been advanced by Mr. Paterson and his assistants, including the investigation of certain patterns of so-called

"glareless" head-lamps for motor-cars, and some work on nitrogen-filled "half-watt" lamps, which go in the direction of indicating the range over which the greatest success is to be expected with lamps of this nature. Some interesting differences in the behaviour of tungsten filaments in nitrogen and in vacuo have already been brought out. It appears that although the nitrogen-contained tungsten filament can be maintained at much higher temperatures, its efficiency at any given temperature is not as high as a larger proportion of the energy is taken away to convection. Another matter being investigated is the ratio of mean horizontal to mean spherical candle-power, and the relation of these various properties to the thickness of the filament will bring out some important points.

Space does not permit of a reference to all matters of electrical interest in other departments, but it may be mentioned in conclusion that the metrology department has in hand the standardisation of bayonet socket lampholders.

## THE OPTOPHONE

ON Tuesday, June 16th, at the Conversazione of the Royal Society (Burlington House), an optophone, invented by Dr. E. E. Fournier D'Albe, was on view. This instrument, which is an example of the ingenious combination of the simple laws of optics, electricity, and acoustics, renders it possible for a blind person to read ordinary type by ear. The construction is shown in the diagram. The light from a Nernst lamp passes through the holes in the perforated rotating disc (A), the prism (B), and the lenses (C), which focus it on to the reading desk at (M), in the form of a bright line consisting of five dots giving flashes of different frequencies. The paper to be read is placed print-side downwards on the desk, so that this line of recurring dots falls on to the print, and is reflected back on to the selenium cell (D). The resistance of this varies with the amount of the reflected light. A telephone receiver (F) is connected in

circuit with this cell and a battery, either directly, or through the Brown relay (E) shown in the diagram. As the line of print is moved slowly across the beam, different notes are heard in the receiver, so that with practice it should be possible to visualise each letter as it passes. In the case of the letter L, for instance: when the upright stem of the letter coincides with the beam, no light would be reflected on to the selenium, and the telephone would be almost silent. As the letter gradually passed to the right, all the dots except the lowest would be reflected, and the telephone would emit a composite note consisting of four simple notes corresponding to each of the four dots. When the letter had passed out of range all the five notes would be heard. Once the reader has learnt to recognise the various combinations of notes, any kind of type can be read. The lenses (C) are for focussing the beam of light to suit the different sizes of print.

**Electric Clocks.**—In a lecture given before the National Association of Goldsmiths at Margate, Mr. F. Hope-Jones pointed out that electric time service had been established in spite of the clockmaking trade, and complained that they knew little of the subject, and had actually put obstacles in the way of the use of electricity in connection with clocks. On the Continent, however, this branch of horology was a recognised part of a clockmaker's education. Mr. Jones also remarked that the loss of keywinding contracts due to the adoption of electric clocks was more than compensated for by supervision contracts. There can be no doubt that, given a fair trial, electricity will be able to prove its superiority for this purpose over purely mechanical methods, as it has done in innumerable other instances.

### THE METROHM

A NEW pattern of insulation tester has recently been put on the market by Everett, Edgecumbe & Co., Ltd. (117 Victoria Street, S.W.), under the name of the Metrohm, which has several points of interest. It consists of a 500-volt magneto-generator, and a direct reading ohm-meter, graduated up to 50 megohms in the standard instrument, contained in a single oak case measuring no more than 7 by 8 by 9 in. The complete instrument weighs a little over 16 lb. Its general appearance is seen in Fig. 1.

The generator is at the bottom of the case, and has an entirely separate field magnet system from that of the ohm-meter, and is driven through a train of gearing by

FIG. 1.—THE METROHM.

the detachable crank handle. It is of specially light construction with substantial ball-bearings, and gives 500 volts when the handle is rotated at 100 r.p.m.

The ohm-meter is mounted on the top of the generator. The field is provided by a large permanent magnet of the same general form as used in ordinary moving-coil instruments, and in the air-gap between its poles and the iron core between them swings the coil, which is in series with the generator and the resistance to be measured in the usual way. The other coil is mounted on the top of it, and is connected with its series resistance across the terminals of the generator, and therefore carries a current proportional to the voltage. It is mounted in a vertical plane making an angle of about  $45^\circ$  with that of the current coil, and moves

FIG. 2.—DIAGRAMMATIC SKETCH SHOWING ARRANGEMENT OF MOVING SYSTEM OF OHMMETER PART OF INSTRUMENT.

in a very much weaker control field produced by extensions of the main pole pieces without any iron core within it. The relative positions of the coils and pole pieces will be understood from the diagrammatic sketch in Fig. 2. In instruments of this class there is no spring control of the moving system, which takes up its position in the field according to the relation between the current in the two coils, and therefore the value of the resistance to be tested. There are,

accordingly, no control springs, but current is led in by ligaments at the top, which exercise practically no directive force. The arrangement of the pivots is similar to that in the ordinary Everett-Edgecumbe moving coil instruments. The pivots are inside the lower coil at the top and bottom respectively, and bear on jewels mounted in plungers inside the core, which is drilled out to receive them. These plungers have springs behind them which hold them up to the pivots when the coil is put in, but are afterwards clamped in the position determined by these springs by set screws. The arrangement is indicated in the sketch. The pointer is strong but light, and gives easily readable indications on the scale. A particular feature of the instrument is the length (5 in.) of the scale, and its openness at the part, especially between 0.5 and 2 megohms, where accuracy is most desirable. This is accomplished mainly by the shape and proportion of the pole-pieces. The standard instrument is graduated up to 50 megohms, but special ranges can be arranged for. There are only two terminals on the outside of the case, and when making a test all that has to be done is to connect these to the points between which the insulation is to be measured, to turn the handle, and to read the scale. As in the case with all instruments of the ohm-meter class, the reading does not depend on the accuracy of the testing voltage, so that the exact speed at which the handle is turned is immaterial. The pointer is particularly dead-beat in its movement, which conduces to very quick readings.

### CORRESPONDENCE

#### THE I.E.E. INDUSTRIAL COMMITTEE.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—There must be many members of the I.E.E. who have but the vaguest notion of the events resulting in the dissolution of the Industrial Committee, and of the real issue between that Committee and the Council. The last Council Report, the speeches at the General Meeting, and the various references in the electrical Press, all fail to enlighten the rank and file to any material extent, though they indicate some strength of feeling. If the late members of the Industrial Committee consider the matter to be of so much importance to the electrical profession and industry as their utterances indicate, surely it is desirable to get the formal opinion of the members as a body on their proposals, for the guidance of the Council, and of everyone concerned. The constitutional method open to them is that of requisitioning a special meeting to discuss a substantive proposition, and the present time, between the sessions, and before the new President and members of Council assume their duties, is opportune. Before such meeting it is desirable that the Council and the late Committee should jointly issue an agreed statement of the events which resulted in the dissolution of the Committee, that members may have an authoritative foundation for their judgment. I write in the interests of the great majority of members, who have not taken sides, who do not know what is really at issue, but feel that it may be of great importance to the Institution itself, and to all interested in electrical work and progress; and that they are entitled both to full information, and to an opportunity of expressing a considered opinion.

11 Knollys Road, Streatham.  
June 22nd, 1914.

I am, yours, &c.,  
HENRY M. SAYERS.

**Experiments with an Incandescent Lamp.**—At a recent meeting of the Physical Society, some curious experiments were described and exhibited by Mr. C. W. S. Crawley and Dr. S. W. J. Smith. The first of these was due to Mr. Addenbrooke, who, using a 100-volt lamp filled with paraffin oil (after removing the tip) as a convenient high resistance in a 200-volt circuit, noticed that some of the many bubbles forming on the filament behaved in a curious way. Instead of rising at once to the surface from the point at which they formed they ran down the legs of the filament, against gravity, and then escaped at the leading-in wires. Dr. Smith, led to repeat this experiment by Mr. Crawley, discovered another, more striking, phenomenon. Placing the 100-volt lamp in a 100-volt circuit in series with a variable resistance, it was found possible, by momentarily cutting out most of the resistance, to obtain a single bubble upon the wire. The behaviour of such a bubble was very interesting to watch. Instead of escaping at either terminal, as in Mr. Addenbrooke's experiment, it travels backwards and forwards between the two, "looping the loops" of the filament in a fascinating way during every journey. The peculiarities of this phenomenon, which can be obtained with either direct or alternating supply, have been examined, and it has been shown, from the experiments, that a rapid fall of temperature from the wire through the liquid, in the region through which the bubble moves, is an essential condition.

## ANNOUNCEMENTS RELATING TO PATENTS.

Small Prepaid Advertisements with regard to Patents, &c., are inserted on this page, facing our Patent Record, at 1d. per word (minimum 5s.); three insertions for the price of two. Rates for displayed, illustrated, and card advertisements on application.

Advertisement matter, accompanied by a remittance, should be addressed to the Kilowatt Publishing Co., Ltd., 203 Temple Chambers, London, E.C.

HERBERT HADDAN & Co., Patent Agents and Consulting Engineers, 31 and 32 Bedford Street, Strand, London, W.C., beg to call the attention of Engineers, Manufacturers, and others to the following important ENGLISH PATENTS, the Proprietors of which are desirous of arranging by license or otherwise, on reasonable terms, for the manufacture and commercial development of the Inventions in this Country:—

IMPROVEMENTS IN DYNAMO-ELECTRIC GENERATORS. No. 16,729 of 1906.

IMPROVEMENTS RELATING TO DYNAMO-ELECTRIC MACHINES. No. 13,330 of 1910.

IMPROVEMENTS IN ELECTRIC LOCOMOTIVES. No. 7,750 of 1908.

For particulars, mentioning number and year of the Patent, address HERBERT HADDAN & Co., Patent Agents and Consulting Engineers, 31 and 32 Bedford Street, Strand, London, W.C.

The Proprietor of British Patent No. 14,383/1910, covering an invention relating to ELECTRIC FIRE ALARMS, is desirous of entering into negotiations for the Sale of the Patent rights or the granting of licenses.

All communications to:—Messrs. PHILLIPPS (Robert E. Phillipps, M.I.Mech.E., Assoc. M.Inst.C.E., and A. Millward Flack, Fel. Chart. Inst. P.A.), 70 CHANCERY LANE, LONDON.

Patent 9,447/13 enables RESISTANCES with large number of contacts, suitable for dimming lights or motor regulation, to be made in compact and inexpensive form. Nothing on the market is as small or efficient. Large sale certain at remunerative prices. Royalty rights or sale outright offered. Alternatively capital required for working. Model can be seen. MANSELL, 13 Cecil Court, London, W.C.

The Proprietor of the Patents 15,991 of 1909 and 26,341 of 1911 for "An Improved ELECTRIC LOCKING and UNLOCKING DEVICE FOR LOCKS," and "Improvements in ELECTRIC LOCKING DEVICES FOR LOCKS," is desirous of entering into arrangements by way of license and otherwise on reasonable terms for the purpose of exploiting the same and ensuring their full development and practical working in this country. All communications to HASELTINE, LAKE & CO., Chartered Patent Agents and Consulting Engineers, 28 SOUTHAMPTON BUILDINGS, CHANCERY LANE, LONDON, W.C.

British Patent 10,605/1912 is for sale for the purpose of immediate manufacture of the patented article. Particularly suitable for HARDWARE or ELECTRICAL FACTORIES. Offers to F. C. A. 485, c/o RUDOLF MOSSE, Frankfurt-on-Maine, Germany.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published June 18th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

**12,115/13. Metallic Conduit Fittings.** SIMPLEX CONDUITS, LTD. An improved form of fitting particularly applicable to ceiling roses. It consists of a metallic box and cover with separate insulating block, which can be removed from the box for connection to the lamp wires. The latter are passed over a rubber ring, which is contained in the top of the block so that an elastic support is obtained. The lower part of the block is made cylindrical, and protrudes slightly through the cover, thus preventing accidental contact of the wires with the cover. Nine figures.

**15,014/13. Heating Units.** L. W. CAMPBELL. A series of mica washers is mounted upon a central supporting rod, and compressed into a solid mass. A thread is then cut upon the resulting bar, and high resistance wire is wound in the grooves of the thread, one end of the wire being connected to the central supporting rod, and the other to a metal sleeve which is mounted upon one end of the insulating bar. A compact and durable heating unit is thus formed. Seventeen figures.

**18,018/13. Telephone Transmission Lines.** WESTERN ELECTRIC CO. (F. T. Woodward). A method of constructing an artificial line to correspond with, or balance, a loaded transmission line. The principle upon which this method depends may be stated thus: The impedance of a long, periodically-loaded transmission line, beginning at the fractional part 0.17 to 0.20 section, may be approximated to, at frequencies below the critical frequency, by a three-branch network consisting of a constant resistance in series with a combination consisting of a capacity in parallel with a high time-constant inductance. If  $L$  and  $C$  are the inductance and capacity, respectively, of the transmission line, the values of the resistance, inductance, and capacity of the artificial line should be  $\sqrt{L/C}$ ,  $0.3 L$ , and  $0.53 C$  respectively. Further particulars are given to suit cases where the loaded line does not begin at about 0.2 section. Three figures.

## Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** B.T.-H. Co. (G.E. Co., U.S.A.) [Vapour lamps] 15,392/13.

**Dynamos, Motors and Transformers:** OTIS ELEVATOR CO. (Otis Elevator Co., U.S.A.) [Motor control] 15,682/13; BOUCHEROT [D.C. transformers] 19,588/13; STORER [Regenerative braking] 21,140/13; SIEMENS BROS. DYNAMO WORKS, LTD., and WILSON [Rotary converters] 29,270/13; SIEMENS SCHUCKERT. GES. [Poly-phase motor regulation] 1,640/14, [Motors for ship propulsion] 4,309/14.

**Electrometallurgy and Electrochemistry:** CRAFTS [Shaft furnaces] 18,073/13.

**Heating and Cooking:** FREAS [Constant temperature ovens] 12,740/13; BRITISH ELECTRIC HEATER CO. and KRATT [Heater for liquids] 16,601/13; RAILING and IDE [Ovens] 17,264/13; SPRENGER [Heaters] 8,719/14.

**Ignition:** WOLF [Engine starters] 26,502/13.

**Incandescent Lamps:** GLADITZ [Manufacture of tungsten] 12,421/13.

**Instruments and Meters:** ELSTER [Electricity meters] 5,157/13; EVERSHED & VIGNOLES, LTD., and EVERSHED [Insulation testing] 12,723/13, 12,032/14; FURSTENAT [Röntgen-ray meter] 29,831/13.

**Storage Batteries:** WEEKS [Accumulators] 26,251/13; SVENSKA AKKUMULATOR AKTIEBOLAGET JUNGNER [Alkaline accumulators] 72/14.

**Switchgear, Fuses and Fittings:** HIGGINS and GRIFFITHS [Ceiling fitting] 18,400/13; JEIDEL [Thermal contact] 3,818/14.

**Telephony and Telegraphy:** SOLDATENCOW [Perforator] 5,352/13; AUTOMATIC TELEPHONE MFG. CO. (Automatic Electric Co.) [Telephone systems] 10,200/13; PLECHER [Telephones] 10,399/13; LUND and NEW PHONOPORE TELEPHONE CO. [Telegraph or telephone calling device] 12,966/13; DITCHAM & GRINDELL-MATTHEWS WIRELESS TELEPHONE SYNDICATE, LTD. [Wireless alarm apparatus] 13,065/13; HEYL and BAKER [Wireless apparatus] 18,024/13; WESTERN ELECTRIC CO. (Woodward) [Telephone receiver] 25,643/13; FITZGERALD and FITZGERALD [Telephone call meter] 27,137/13.

**Traction:** WHITE (Sturges) [Electric railways] 15,658/13.

**Miscellaneous:** STIBBE [Knitting machines] 16,349/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, Cables and Wires, &c.:** SIEMENS SCHUCKERT. GES. [Tightening overhead conductors] 13,213/14.

**Dynamos, Motors and Transformers:** GRAEMIGER [Motors] 8,699/14; FIORANI [Dynamo-electric machines] 11,159/14; OTTO [Converter] 11,561/14; CIE DE L'INDUSTRIE ELECTRIQUE ET MÉCANIQUE [Dynamo electric machines] 13,159/14.

**Incandescent Lamps:** WESTINGHOUSE METALLFADEN GLUHLAMPEN FABRIK [Lamp manufacture] 12,358/14, 12,359/14.

**Switchgear, Fuses and Fittings:** FELTEN UND GUILLAUME CARLSWERK AKT. GES. [Circuit breakers] 12,934/14.

**Telegraphy and Telephony:** BETULANDER [Automatic and semi-automatic systems] 6,210/14; GILES [Condensers] 10,895/14.

**Traction:** SIEMENS SCHUCKERT. GES. [Cooling of electric locomotives] 25,497/13.

**Miscellaneous:** SONTOG [Talking machines] 12,666/14.

The following Amended Specifications may now be obtained:—

**Distributing Systems, Insulating Materials, &c.:** B.T.-H. Co., LTD. (G.E. Co., U.S.A.) [Insulating material], 3,566/13.

**Incandescent Lamps:** A. JUST [Tungsten filament manufacture] 4,034/13.

**Miscellaneous:** R. IMME [Typewriter], 4,405/13.

## Opposition to Grant of Patents

**13,282/12. Manufacture of Ductile Masses of Tungsten, &c.** DR. ING. P. SCHWARZKOFF, S. BURGSTALLER, and WOLFRAM LABORATORIUM DR. ING. P. SCHWARZKOFF. The Comptroller has allowed the grant of this Patent notwithstanding the opposition raised. (See ELECTRICAL ENGINEERING, May 28th, 1914, p. 295.)

## Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

**11,562/00. Mercury Vapour Lamp.** P. COOPER HEWITT. The body of the lamp consists of a long glass tube with the upper end enlarged to form a cooling chamber. The anode is of pure iron and the cathode of mercury. The leading-in wires are of platinum fused into the glass body at each end. A small quantity of sulphur is introduced into the cathode mercury, to facilitate the starting of the lamp. In constructing the lamp, the mercury is heated before the lamp is sealed off, and a potential is applied to the terminals, so that the mercury is vapourised and all other gases which may be occluded in the anode or cathode are driven out. The tube is then hermetically sealed. The internal pressure when cool should be from 2 to 8 mm. A thin metallic band is fixed on the outside of the tube near the anode, and is electrically connected to the cathode, its object being to facilitate the starting of the lamp. An induction coil may be used for obtaining the high initial voltage necessary for starting. A lamp  $\frac{3}{4}$  in. dia.  $\times$  57 in. between electrodes with a condensing chamber  $2\frac{1}{2}$  in. dia. requires about 3 amps. at 110 volts. Five figures.

**11,835/00. Pneumatic-Electric Control.** E. R. HILL. A system of motor control by which all the controllers on an electric train can be operated synchronously. The operating handle of the master control can be turned so as to complete the circuits of electromagnets which admit compressed air to the cylinders which operate the reversing switches of the several motors. Another movement of the operating handle energises the electromagnets, admitting air to the cylinders which move the motor controllers one notch forward. The circuit is then automatically broken and remade, so that the above operation is repeated and the controllers move forward step by step to their "on" positions. When the brakes are applied, the power circuits are simultaneously and automatically opened. Sixteen figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** A.E.G. [Titanium oxide and iron electrodes] 4,762/08.

**Dynamos, Motors and Transformers:** C. A. PARSONS [Armature winding] 5,374/02; MORGAN CRUCIBLE CO. and C. W. SPIERS [Brush holders] 5,167/06; N. W. STORER [Commutator connections] 3,831/09; B.T.-H. Co. (G.E. Co., U.S.A.) [Rotary transformers] 5,119/09, 5,209/09; F. BURKS [Magneto machines] 8,489/09.

**Electrochemistry and Electrometallurgy:** H. BIRKBECK (C. G. Hoffmann) [Tempering metals] 5,124/08.

**Heating and Cooking:** C. RUZICKA [Resistance material] 4,657/08.

**Ignition:** R. BOSCH [Spark plug] 15,985/09.

**Storage Batteries:** J. E. G. MÉRAN [Magnesium silicate casing for plates] 5,366/02.

**Switchgear, Fuses and Fittings:** R. H. W. KNIGHT and L. NAGEL [Metallic conduits] 5,240/03.

**Miscellaneous:** F. J. KING [Magnetic separator] 5,209/02; F. BURKS [Improving magnetic qualities of cast-iron] 5,360/09.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,397.

A fault occurs on a 7/16 3-core paper, lead-covered and armoured cable 300 yds. long, laid direct. On testing, it is found that each core has gone to earth, and also burnt clear from the remaining portion of the cable. Two-thirds of the cable is in the middle of a road at a depth of 3 to 5 feet, the remainder under paving-stone in the pathway. State the most reliable test for locating this fault to avoid opening up as much as possible.—"ADSUM."

(Replies must be received not later than first post, Thursday, July 2nd.)

### ANSWERS TO No. 1,395.

A three-phase slip ring motor controlled by a reversing type controller, drives a tramcar, and in coming down a steep incline the car runs away and the brakes refuse to act. Can the motor when driven up to or above synchronous speed by the momentum of the runaway car be utilised as an induction generator feeding back to the line, and act as a brake on the car? In what position should the controller be put, i.e., to run the motor in the same direction of rotation or to reverse it, and to get the maximum brake effect as an induction generator should all resistance be cut out of rotor circuit? What is the relation of brake effect and speed of motor under such conditions? What would be the effect of attempting to reverse the motor while the car was running away.—"PUZZLED."

The first award (10s.) is made to "DARNOC" for the following reply:—

When an induction motor is driven above synchronous speed by external means the motor acts as an induction generator, and supplies power to the line.

To make use of this property of the machine, to obtain a braking effect, the controller should be kept in the forward position. To obtain the maximum braking effect some resistance should be cut into the rotor circuit; the amount of this to obtain maximum resisting torque depending on the speed which the motor has attained over synchronism, the resistance being reduced as speed gets nearer synchronism. The reason for this is shown in the attached "speed-torque" curve. It will be seen that the induction generator characteristic is somewhat similar to the characteristic of the machine as an induction motor, but of the opposite sign, and it will be seen that a point of maximum resisting torque is reached (which corresponds to the "pull-out" point of the machine running as an induction motor).

The effect of cutting-in rotor resistance is to move this point further away from synchronism, the speed above synchronism (or negative slip) being proportional to the total resistance in the rotor circuit (i.e., internal and external). The object, therefore, of cutting-in resistance into the rotor circuit is to obtain this maximum resisting torque at the speed at which the motor is being driven.

Referring now to the effect if the controller be put into

the reverse position, this will be the same thing as if the motor were driven backwards; it is shown on the curve that a torque will be developed, and as the machine is reversed, this will be a resisting torque, but this will not be as great as in the preceding case, and, further, the braking effect

### REFERENCE.

- 1 = Without Rotor Resistance.
- 2 = With two different Values of
- 3 = Rotor Resistance in Circuit.
- T = Points of Max. Torque.

will be obtained by means of the motor absorbing power in its own windings (and in the rotor resistance if this is in circuit). This is obviously very undesirable, especially as large currents are induced in the rotor windings with consequent probable damage.

The second award (5s.) is given to "A. L.," who writes as follows:—

This question deals with the possibility of regenerative control for induction motors. Any induction motor, if run above synchronous speed, will act as an induction generator, provided that its terminals are connected to a suitable A.C. supply to provide the exciting current necessary to maintain the rotating field, as this form of generator is not self-exciting. A special feature of the induction generator is that it is "asynchronous," or that its frequency is independent of the speed, and is determined by the frequency of the supply to which it is connected. The output as a generator is proportional to the slip or difference between actual speed and synchronous speed for small values of slip, say up to 9 or 10 per cent. slip, thus being similar to the induction motor. In the question the driver of the car has apparently brought his controller to the "off" position on a down grade, and attempted to apply his brakes and found the latter inoperative. Meanwhile, the car has been gathering speed, and is now running away, i.e., travelling above full speed, and still speeding up. If he notch up his controller in the "forward" direction he will make use of the generator action of his motor to brake the car. This action will be strongest when he is in "full forward" with all rotor resistance cut out, the current carried by the stator then being a maximum. It must be noted, however, that it is impossible to stop the car by this means, as the braking action only persists so long as the car is travelling above its maximum speed. The braking will be proportional to the output as a generator, hence to the slip, and a point of equilibrium will be reached at about 5 per cent. overspeed, at which the motor will hold the car. To stop the car, however, it will be necessary to reverse. This is effected by interchanging two of the three phases. The phases interchanged represent a "short" on the lines, but owing to the inductance of the motor, full volts, applied to the stator, with rotor shorted and standing, results in about 5-6 times normal full-load current passing through stator. Owing to the generator action, though, when motor is running above synchronous speed, this would be nearly doubled, but the first reverse notch of the controller inserts all the rotor resistance, reducing the short-circuit current by about 50 per cent. The motor overload protection may be fuses which should carry this current for a minute or two, whilst car is pulling up, or overload switches. If the latter are set too lightly, then wedge the trip coils.

## ELECTRIC TRACTION NOTES

The Bill promoted by the Metropolitan & Great Northern Railway Companies which sought powers jointly, to work the Great Northern & City Railway, to link up that line with the City & Waterloo Tube Railway at the Bank, and also to link up with the Metropolitan & District Railways, has been withdrawn by the promoters. It has been under consideration for several days by a House of Commons Committee, who passed the preamble subject to certain conditions which the promoters regarded as too onerous. These conditions included a compulsion to electrify the connecting lines between the Great Northern & North London systems between Finsbury Park and Canonbury, and that no goods traffic be allowed upon the Great Northern & City Railway.

The Annual Congress of the Tramways and Light Railways Association will be held at Newcastle on July 16th and 17th. The following Papers are down for reading:—"Some Features of Newcastle Corporation Tramways," by Mr. R. Mayne; "Tramway Experiences in Brazil," by Mr. H. M. Sayers; "Standard Tram Rails," by Mr. F. Bland; "Rail Joints," by Mr. R. Humphries; and "Town Planning," by Mr. J. A. Brodie.

A proposal that the Aberdeen Corporation should purchase the Aberdeen Suburban Tramways Co. has been received with favour by the majority of the members of the Corporation.

At the meeting of the British Electric Traction Co. last week Mr. E. Garcke, who was in the Chair, announced that the year's net revenue of all the federated companies amounted to £1,200,000, after paying all working expenses, of which the B.E.T. Co. received about £200,000. The yield on their investments was 4.47 per cent., as compared with 4.11 per cent. for the previous year. This, he said, was higher than for many electrical undertakings. A scheme for rearrangement and reduction of capital is under consideration.

At a meeting last week of the Underground Electric Railways Co. of London, resolutions were adopted converting the Company formally into a share and securities holding company. Sir Edgar Speyer said that the Company had long

completed the constructional work that it undertook, and had disposed of its power-house to the Metropolitan District and London Electric Railways Co.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The final report of Mr. G. Franklin, the liquidator of the National Telephone Co., states that the deferred shareholders have been repaid their holding at par plus a premium of 5.48 per cent. The expenses of the arbitration proceedings and liquidation are equivalent to 1.32 per cent. of the total amount realised.

The liner *Royal George* has been equipped with the Marconi-Bellini-Tosi wireless compass, or radio-gonometer, by which she can find her position when within fifty miles of a wireless station, and can tell accurately the bearings of ships from which signals are received. The steamer *Eskimo*, plying between Hull and Christiania, has been using this apparatus for some months.

The net profit for the year of the Marconi International Marine Communication Co. is £37,029, against £24,496 for the previous year. The Company owns and works 873 public stations on the high seas, and there are now some 2,000 merchant ships fitted with Marconi apparatus. A final dividend, making 10 per cent. for the year, is recommended.

A wireless station has been opened on the Island of Waigatsch, near Archangel, in the Arctic Ocean.

The wireless stations at Tobermory and Lochhoisdale have been temporarily closed.

It is reported that the breakage of a cast-iron telephone pole by collision with a van caused no less than seventeen adjoining poles to be brought down at Brighton last Friday.

Deferred telegrams for Bolivia are now accepted "via Colon."—The Heliograph station between Ponta Padrao and Soca Province of Angola is interrupted.—The only offices which can now be reached via Libreville Loango are Landana, Cabinda, Lela, and Soca.—Defective lines beyond Adana and Sivas cause delay to telegrams for Syria and Irak.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 377. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**STEAM TURBINES.**—The latest list of Curtis steam turbines issued by the British Thomson-Houston Co., Ltd. (Rugby) contains particulars of several hundred turbines aggregating 384,594 kw. sold by the company up to April 30th last.

**CHLORIDE ACCUMULATORS.**—Some interesting particulars of the varied uses to which accumulators have been successfully applied are to be found in a pamphlet recently issued by the Chloride Electrical Storage Co., Ltd. (Clifton Junction, Manchester). Charts are reproduced showing how a battery of accumulators in conjunction with a booster may be used to remove the load fluctuations from a generator, thus enabling a high efficiency to be attained. Other cases in which a battery has been found advantageous, such as, for the operation of a swing bridge, locomotives for tunnel excavating, and railway platform trucks, are also mentioned.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

**ACCUMULATOR CARS.**—Edison Accumulators, Ltd. (2 and 3 Duke Street, Piccadilly), have issued an attractive new catalogue of private passenger cars driven by Edison batteries. The chassis is manufactured by Arrol-Johnstone, Ltd. (Paisley and Dumfries), and is arranged with part of the battery in front and part in the rear. A single motor is employed driving through a worm and differential. Some very handsome bodies are illustrated, ranging from the small three-passenger standard coupé, which many of us have seen on the road, to commodious domed limousines representing the last word in luxury and elegance.

**WIRELESS TIME SIGNALS.**—The compact wireless receiving set known as the Horophone, by the aid of which the time signals from Paris and Norddeich can be picked up, is illustrated in a new booklet from the Synchronome Co., Ltd. (32 and 34 Clerkenwell Road, N.). Instructions are also given for the interpretation of the weather reports which are sent out from Paris each day.

**ILLUMINATION.**—An attractive little folder just issued by the British Thomson-Houston Co., Ltd., entitled "Economy by Reflection," deals with the use of scientifically designed shades and reflectors, and lists reflectors of the Veluria, Holophane, Opalux, and Sudan types of glassware. These holders can be overprinted with contractors' names and addresses.

**THE BRUSH BUDGET.**—A number of motor-generator sets and motors for special purposes, and some examples of cotton-mill drive are illustrated in the May number of the Budget of the Brush Electrical Engineering Co. (Loughborough).

**CONDUITS.**—A new leaflet, giving prices of conduits and conduit fittings, has been issued by Krupka & Jacoby, Ltd.

**IRONCLAD SWITCHGEAR.**—A leaflet from J. H. Holmes & Co. (Newcastle) deals with high-tension ironclad switchgear of the draw-out type for mining and sub-station work. This is of very substantial construction, and is fully interlocked.

**BELLS AND ACCESSORIES.**—A comprehensive new catalogue of electric bells, batteries, pushes, and other accessories has been issued by the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex). A very complete range of apparatus is dealt with.

**INSULATING MATERIAL.**—A folder from Carson & Evans (3 Fenchurch Buildings, E.C.) calls attention to their special Carvanite insulating material, which is claimed to have superior qualities to ebonite at a lower price.

**THE "E.C. JOURNAL."**—The June issue of this illustrated journal, published by the Electrical Co., Ltd., contains an article on electric chicken incubators and description of various parts of the factories in which the Company's products are made, with some notes on the latest developments in polyphase meters.

### THE CALORITE COOKING STOVE

THE form of electric stove illustrated here has recently been introduced by the British Thomson-Houston Co., Ltd. (Rugby), and is the result of considerable experience in the manufacture of heating devices. It can be used for boiling water, and several other simple cooking operations. The machined face of the hot-plate is  $6\frac{1}{4}$  in. square, and is

THE CALORITE ELECTRIC STOVE.

clamped to a frame standing on porcelain feet. The heating element, which consumes 1,000 watts, is of the special Calorite alloy, which withstands oxidation up to a very high temperature, and has a melting point of  $2,800^{\circ}\text{F}$ . The terminals are substantially made and well protected. A pint of water can be boiled in eight minutes, starting with the stove cold, or five minutes if the stove is hot.

### COMMUTATOR GRINDING

APPARATUS for commutator grinding is sometimes fitted with an automatic feed arrangement, but there are many cases where the expense of this is not justifiable, and non-automatic apparatus is preferable. For such work the Witton-Kramer Electrical Tool and Hoist Co., Ltd. (Witton, Birmingham), for whom the General Electric Co., Ltd. (67 Queen Victoria Street, London, E.C.), are the sole selling agents, supply a special pattern of long-snout grinder. One of these is shown in the accompanying illustration grinding the commutator of a 750-kw. rotary converter. The method

WITTON-KRAMER GRINDER IN USE ON COMMUTATOR OF 750 KW. ROTARY CONVERTER.

of fixing the grinder is very simple. The bolts for the bearing cap are slackened, and a pair of suitably bent angle irons inserted between the bearing cap and the pedestal, the bolts being screwed down again tightly to hold the angle irons, which are cut away to receive the bolts. The slides for the

grinders are bolted on the horizontal platform formed by the two angle irons. The grinder has the usual two motions. The whole arrangement is very rigid and gives a true surface to the commutator. On account of the simplicity of the arrangement it is possible to equip a generator or motor with this grinder in considerably less time than an automatic machine would take. When the distance between adjacent brush sets is small, it is necessary to remove one set of

brushes. In the illustration, the second set has been removed so as not to obstruct the view of the grinding wheel. Special arrangements for driving the armature at reduced speed are generally unnecessary, and it is sometimes possible to undertake the grinding with the machine on load. A special insulating grinding wheel is available for this purpose, so that no danger of earthing exists. Also the wheel can be fixed to grind at the point of zero potential. Rotary-converters with starting motors can be run off the starting motor during grinding, or can be driven from the continuous-current side at either full or reduced speed; while generators can be driven from the engines or run from the bus-bars as motors.

### BASTIAN METERS

IMPORTANT reductions in the price of Bastian meters have been made, which should help considerably to reduce the cost of connecting up cottages and small houses. We are informed that every meter made by the Bastian Meter Co. is guaranteed to start on and to register correctly the current consumed even by a 10 watt lamp, and even a leak on the house wires is recorded. With the present tendency towards cheaper units and higher efficiency lamps this question of starting current becomes more and more important, and should be taken into very careful consideration when the meter problem is being considered. Another great advantage claimed is that there is nothing to wear out, or to require periodical adjustment. The prices now range from 10s. 6d. for the 3 ampere meter to 15s. for the 5 ampere instrument. These meters are usually selected so as not to require resetting more than once a year on the average, and the makers do not claim that the Bastian meter is suitable for every class of consumer, but only for most small consumers.

**R.A.C. Motor-car Accessory Trials.**—We have received a long letter from Rushmore Lamps, Ltd., dealing with the nature of the trials of motor-car accessories organised by the Royal Automobile Club. The firm assert that the weak point from the users' point of view of these trials is that the Club direct their attention only to points in the apparatus tested which the makers desire to be tested, and that weak points are liable to be missed in this way. They suggest that the Club should have a freer hand to investigate any points that they like in the apparatus submitted, and express their willingness to submit one of their engine-starter and lighting equipments to be tested on the Club's own conditions.

**The New Pirelli Cable Works.**—Two illustrations in the *Southampton and District Pictorial* show views of the western shore at Southampton in 1774 and 1914 respectively. In the latter the new Pirelli cable works is shown to be rapidly approaching completion.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Beckenham.**—Tenders are to be invited for an evaporative condenser and one 120-kw. D.C. generating set.

**Oldham.**—Further generating plant is to be purchased at a cost of about £40,000, in view of the increasing power load.

**Rawtenstall.**—The Local Government Board has sanctioned a loan of £99,900 for the electricity undertaking, and a separate loan of £1,000 for electric street lighting.

**Rochdale.**—Tenders are invited for a wet air filter by July 1st. Particulars from Mr. C. C. Atchison, Electrical Engineer, Dane Street, Rochdale.

**Southport.**—Electric fans will probably be required for the ventilation of the Market Hall.

**Walsall.**—A Local Government Board inquiry was held last Thursday regarding an application for a loan of £74,850 for a new electricity works.

### Wiring

**Manchester.**—Tenders are invited for electric lighting installation at Mill Street Industrial Day School, Ancoats. Particulars from Secretary, Education Office. Tenders by June 30th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Bath.**—Drill hall, &c. Lower Bristol Road, Bath. Architect, A. J. Pictor, Bruton.

**Cornholme.**—Cinematograph theatre. Architect, J. E. Stote, Bridge Street, Todmorden.

**Gillingham (Dorset).**—New post office. H.M. Office of Works.

**Liverpool.**—Cinematograph theatre in Lime Street.

**London: Tooting.**—Extensions to Tooting Bee Asylum. Architect, T. W. Aldwinkle, 20 Denman Street, London Bridge, S.E.

**Stoke Newington.**—Extensions to Town Hall.

**Margate.**—Extensions to children's hospital. Architect, T. W. Aldwinkle, 20 Denman Street, London Bridge, S.E.

**Middlesbrough.**—Elementary school at Grove Hill.

**Radcliffe.**—New premises, Manchester County Bank. Architects, Mills & Murgatroyd, 23 Strutt Street, Manchester.

**Sleaford.**—Isolation hospital.

**Torquay.**—New theatre. Architect, F. G. Moore, 9-10 Fleet Street, Torquay.

### Miscellaneous

**London.**—Tenders for a three years' supply of electrical accessories are invited by H.M. Office of Works by Sept. 1st. (See an advertisement on another page.)

**Norway.**—The Norwegian State railway invite tenders by June 29th for electric clocks for the Narvik district. Particulars from Distriktschefens Kontor, Norges Statsbaner Narvik. Local representation required.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Lossiemouth.**—A contract for wiring the Town Hall, Court Room, and Library has been given to Primrose & Primrose at £42, including plain fittings.

**Rugby.**—The tender of W. T. Henley's for a supply of cable has been accepted.

Siemens Bros. Dynamos Works, Ltd., have obtained a contract for twelve months' supply of Tantalum lamps for ship lighting and Wotan lamps for office lighting from the Royal Mail Steam Packet Co.

## APPOINTMENTS AND PERSONAL NOTES

We refer this week to the Knighthood which has been conferred upon Mr. J. F. C. Snell, President-Elect of the Institution of Electrical Engineers. There was a number of other honours included in the Birthday Honours List which are of some interest to the electrical industry. Sir J. W. Benn, who was so intimately connected with the initiation and development of the London County Council Tramways, has been created a Baronet, as also has Sir Joseph Beecham, who for many years has been, and still is, Chairman of the St. Helen's Electric Lighting Committee. Mr. Albert H. Stanley, Managing Director of the Underground Electric Railways Co. of London, and of the London General Omnibus Co., has been made a Knight.

On Friday afternoon the staff and employees of the Walsall Corporation Electricity Department took their formal farewell of Mr. A. S. Barnard, the Borough Electrical Engineer, who is severing his connection with the Corporation at the end of the present month, and asked his acceptance of a suit-case and a silver rose-bowl for Mrs. Barnard.

Mr. H. A. Howie, who has been appointed Electrical Engineer at Walsall, has been presented with a silver tray and pipe by his colleagues at Sheffield, where he has been in the Electric Supply Department for five years.

Mr. E. Jackson, of Guildford, has been appointed Third Engineer-in-Charge at Bermondsey out of 100 applicants.

The salary of Mr. T. Hall, Borough Electrical Engineer, Burton, has been raised from £275 to £400 per annum, and that of Mr. A. B. Slater, Tramways Manager, from £200 to £220. The salaries of four of the Charge Engineers have also been increased.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £63 5s. to £63 15s. (Last week, £64 to £64 10s.)

**Bankruptcies.**—A second and final dividend of 9d. in the £ is declared in the bankruptcy of T. L. Callender, of Nottingham, Electrical Engineer.

**Change of Address.**—Krupka & Jacoby, Ltd., are removing their offices and stores to 39 Victoria Street (Goods Entrance, Old Pye Street), Westminster. The telegraphic address will still be "Acromion," but the new telephone numbers will be Victoria 6644 and 6645.

**Successful Claim for Commission.**—Messrs. Lindeck, Cahn & Co., stockbrokers, were successful in the action heard by the Common Serjeant last week for commission from the Dubilier Electrical Syndicate in respect of an introduction to the General Electric Co., who have acquired rights under some of the defendants' patents for high-frequency apparatus.

**CAPPER PASS & SON, Ltd.,**  
Bedminster Smelting Works, BRISTOL  
SELLERS OF  
**ANTIMONIAL LEAD OF ALL GRADES**  
BUYERS OF  
**LEAD ASHES & LEAD RESIDUES FROM ACCUMULATORS**  
Telegrams: "PASS, BRISTOL." Telephone: 8475 & 8476.

**BLAKE & INSULATING STAPLES**  
Write for Samples and Prices.  
**MOSSÉS & MITCHELL,**  
Olliswell Works, 122-124, GOLDEN LANE, E.O.

## LOCAL NOTES

### **Belfast:** *Linking-up of the Traction and Lighting Supply.*

—The installation of converting plant is recommended in a report by Sir John Snell to link up the lighting and traction plant, so that each can help the other on peaks, as being preferable to the putting down of a battery which had been proposed. This would entail a saving of about £7,500 over the battery scheme.

**Blackpool:** *Interruption of Supply.*—Last week the bursting of a main steampipe in the station caused an interruption of supply to the lighting and tramways for over half-an-hour. Nobody in the station was injured.

**Blackrock:** *New Power Station.*—The proposed site for a new electricity works has not been agreed to by the Local Government Board, who have signified, however, that on a competent engineer's favourable report and with the approval of the Board of Trade they will reconsider the matter.

**Colwyn Bay:** *Destructor Scheme.*—Mr. E. M. Lacey's suggested scheme for a destructor generating plant at Brouyant has been adopted, and he has been appointed to carry it through.

**East Grinstead:** *Electric Supply Scheme.*—A special meeting of the Council last week had under consideration a proposal for the inception of an electric supply scheme in connection with the refuse destructor which is about to be constructed. A Committee was formed to go into the matter, which is to be reported on by Mr. J. B. Morgan, Electrical Engineer to the Horsham Council.

**Ellon:** *The Lighting Scheme.*—The proposed agreement between the Council and the Company for an electric supply to the Borough, has been unanimously agreed to by the Council.

**Glasgow:** *A Peculiar Accident.*—In making excavations for a drainage gully last week a workman struck a conduit carrying cables with his hammer and caused a serious short-circuit, and was rather badly burned. A temporary interruption to the supply of a small section of the network was caused, but the damage was soon repaired.

**Lynn:** *Electricity Accounts.*—A net surplus of £876, which remains after meeting all capital charges, is to be applied to reduction of capital.

**Middlesbrough:** *The Profit on the Electricity Undertaking.*—In view of the net profit on the undertaking of £3,814, the small consumers, who pay 4d. per unit while the average price received is 1'68d., consider themselves hardly used.

**Morecambe:** *Illuminations.*—The Engineer is to prepare a scheme for illuminating the front during a fishing festival in September; the Committee which is developing the advertising of the place will ask the Corporation to supply current free.

**Rugby:** *Electricity Accounts.*—A profit of £800 has been made on the electricity undertaking, which now supplies about 400,000 units per annum.

**Shrewsbury:** *Electricity Accounts.*—A final surplus of £127, as against £98 for the previous year, is reported.

**Truro:** *Proposed Electric Supply Scheme.*—A public meeting has been held to consider a scheme explained by Dr. Purves, Consulting Engineer to the Council. There is opposition by the local gas interests.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**General Electric Co.** The directors report net trading profits of £157,893, with £32,331 brought forward. After payment of debenture interest and preference dividend and allocating £24,328 to depreciation and removal expenses, an available balance of £133,896 remains. Of this, £14,000 is absorbed by expenses of new issue of capital. £30,000 is recommended to be placed to reserve, £13,156 to bonuses and staff benevolence. Finally, a dividend of 10 per cent. is recommended on the ordinary shares, with £36,739 carried forward. The meeting will be on July 2nd.

**Aron Electricity Meter.**—A dividend of 7 per cent. is recommended on the ordinary shares, with £15,000 carried to reserve. The meeting will be held on June 30th.

**Victoria Falls & Transvaal Power.**—A profit of £467,823 is reported, an increase of £21,444 over that for the previous year. The interest charges and depreciation contributions are, however, larger, so that the net available balance (£225,198) is only £9,831 in excess of last year. The 6 per cent. dividend on the preference shares is paid, but these are still 6 per cent. in arrear. The extension of plant will, however, soon be at work.

**Consolidated Diesel Engine Manufacturers.**—A petition for the winding up of the Company has been presented, and is down for hearing on June 30th. The shareholders have been notified of a meeting to consider a resolution for the voluntary winding up of the Company, with Sir W. Peat as liquidator. There have been some difficulties in the underwriting of a scheme for fresh capital, but if these are overcome in time it will be open to the shareholders not to proceed with the liquidation. The circular gives the excess of assets over liabilities as £320,313.

**R. Waygood & Co.**—A dividend making 6 per cent. for the year is recommended, with £6,156 carried forward.

**J. G. White & Co.**—A profit of £70,387 is reported, a 12 per cent. dividend is recommended, and an extra 10s. per share on the ordinary shares, with £15,000 to reserve and £21,766 carried forward.

**Electric & General Investment Co., Ltd.**—A gross profit of £15,281 is reported. A final dividend of 1s. per share, making 10 per cent. for the year, is recommended, after payment of debenture interest and preference dividends, with £3,285 carried to contingencies fund.

## NEW COMPANIES

**ELECTRIC FLOOR MACHINE CO.,** 86 Hatton Garden, E.C. Capital £3,000.

**BROUGH ELECTRIC LIGHTING CO.**—Capital £1,500. To carry on the business of an electric lighting company at Brough, Westmorland.

**G.M. WIRELESS PATENTS SYNDICATE,** 2 Coleman Street, E.C. Capital £3,000. To acquire patents relating to wireless telegraphy and telephony.

**ELECTRICAL FINANCE & SECURITIES CO.,** 3 Laurence Pountney Hill, E.C. Capital, £50,000. To invest in the securities of electrical, engineering, telephonic and telegraphic appliance, tramway, railway, power, light, and similar companies, &c. The signatories are G. H. Nisbett, J. Taylor, D. Sinclair, E. K. Muspratt, J.P., J. S. Harmood-Banner, D. Bates, and W. B. Cowrie.

**BRITISH WILLARD BATTERY CO.,** 37 Bedford Row, W.C. Capital, £10,000. To adopt an agreement with the Willard Battery Co. of Cleveland, U.S.A.

**ELECTRO-STEEL FOUNDRIES,** registered by Tunbridge & Co., 17 Waterloo Street, Birmingham. Capital £45,000. Private company.

**UNITED STATES RAILLESS ELECTRIC TRACTION.**—Registered by Jordan & Sons, Chancery Lane. Capital, £1,000. Private company.

**HEMMING CONDUIT GRIP.**—Lincoln's Inn Chambers, Corporation Street, Birmingham. Capital, £2,000. Directors, A. E. Beck and J. R. A. Hemming.

**Gas Co. and Electric Hiring at Ilford.**—An interesting action is pending between the Ilford Gas Co. and the Ilford U.D.C. The allegation is that the Council's Electricity Department is spending money illegally in electrical fittings, and also that preferential rates are being given in the matter of power charges. The matter was before the Chancery Courts last week when, on behalf of the Corporation, it was agreed not to enter into any more sales with regard to fittings, pending the hearing of the action. It was also intimated that the case might go to the Court of Appeal.

**Death in an Electric Bath.**—At an inquest recently at Hellingly Asylum on the death of a patient while under treatment in an electric bath, it was found that the death was due to heart failure, and no blame attached as to the management of the bath.

**Wiremen's Wages in Liverpool.**—With reference to the agitation for increased wages to wiremen in Liverpool mentioned in ELECTRICAL ENGINEERING, May 21st, page 278, it is now announced that the wages of all union wiremen have been reduced from 9½d. to 9d. per hour from last Saturday. A rate of 1s. per hour had been asked for. The Liverpool masters did not see their way to granting a higher rate than in force in Manchester. It is reported that 400 men are out on strike.

## SUMMARY

A NEW power station of an ultimate capacity of 140,000 kw. generating at 20,000 or 30,000 volts is projected at Glasgow. (Page 380.)

THE Helsby Wireless Telegraph Co. is being sued by Marconi's Wireless Telegraph Co. in respect of an alleged infringement of Patent No. 7,777/00. An account of the proceedings is given. (Page 381.)

THE North Metropolitan Electric Power Co. has been authorised by a House of Commons Committee to take a supply of electrical energy in bulk from the Metropolitan and London and North Western Railway Companies. (Page 381.)

THE Blackhall Colliery of the Horden Collieries, which is described in a Paper by Messrs. J. J. Prest and J. Leggat, is worked entirely by electric power. (Page 382.)

A PAPER by J. Davidson before the Institution of Mining Engineers dealt with the employment of gas engines in colliery generating plant. (Page 382.)

AN electrically-worked furnace pusher in a South Wales steel works is illustrated. (Page 383.)

AN explosion-proof circuit-breaker and the use of lifting magnets in steel works are referred to. (Page 384.)

A METHOD of manufacturing a steel with very low hysteresis factor, communicated to the B.T.-H. Co. by the G.E. Co. of America, is described amongst the mining and metallurgical patents. (Page 384.)

THE calculation of currents and resistances in branched circuits is dealt with in our Questions and Answers columns. (Page 385.)

AMONGST the specifications published last week was

one dealing with the manufacture of ductile tungsten and another relating to mercury rectifiers. Opposition has been entered to the grant of two patents. (Page 386.)

AN illustration is given of the ovens at the G.E.C. Carbon Works, Witton. (Page 387.)

IN his report upon the railway accident at Burntisland, on the North British Railway in April, Major Pringle calls attention to the fact that three of the coaches involved were lighted by gas and the remainder by electricity, and he attributes the origin of the fire to the gas.—Although the past year's working of the L.C.C. tramways show a deficit of £88,520, this result is arrived at after the payment of £328,109 interest and £108,488 repayment of capital. Steps are to be taken to improve the working of the tramways by further linking up and doing away with dead ends. (Page 387.)

THE present position of the Imperial wireless scheme was outlined in the House of Commons last week.—Automatic telephone exchanges are to be tried in Norway at a cost of £55,000. (Page 387.)

ILLUSTRATED articles in our Trade Section deal with the lighting of the temporary Congress Hall of the Salvation Army, the indirect lighting of a bandstand, and electric fans. (Pages 388 and 389.)

NEW plant is required at Eastbourne, Colwyn Bay, Glasgow, Warrington, Marylebone, Truro, Walsall, Bombay, Aylesbury, and Blackrock.—An electric lighting scheme is under consideration at Crook, and the Willesden Guardians are considering putting down its own generating plant. (Page 391.)

INCREASES in the demand for current for heating and cooking are reported at Marylebone, Brighton, Hull, and Eastbourne. In the latter place, however, the Committee is urged to reduce the present charge of 1½d. per unit.—The Southport electrical contractors are dissatisfied with the decision of the Electricity Committee to open showrooms and hire out cookers and heating apparatus.—Fifty-one chimneys have been put out of use at Bury by firms who are taking electrical energy from the Corporation.—The Board of Trade has refused to grant the Ely Gas and Electricity Co. electric supply powers. (Page 392.)

THE possibility of reducing the fuel costs in power stations to 0·07d. per unit by the use of gas produced on the low temperature system of carbonisation was referred to at the annual meeting of Coalite.—The Trafford Power & Light Supply Co. anticipate receiving an offer for purchase in the near future now that the proposal of the Manchester Corporation has fallen through. (Page 392.)

**The Engineering and Machinery Exhibition, 1916.**—Arrangements are now very far advanced in connection with the Engineering and Machinery Exhibition which is to be held by the Machine Tool and Engineering Association at Olympia from September 28th to October 18th, 1916, and copies of the Rules and Regulations have now been issued, together with a plan and application forms for space and power supply.

## ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JULY 2ND.

*Institution of Civil Engineers.*

8.30 to 11.30 p.m. Annual Conversazione.

WEDNESDAY, JULY 8TH.

*Diesel Engine Users' Association.*

4 p.m. Meeting at Institution of Electrical Engineers, Victoria Embankment.

### The London Electrical Engineers.

Henceforth, until a date in October to be announced later, Headquarters will remain closed for drill purposes.

Headquarters will be opened daily for transaction of regimental business from 10 a.m. till 4 p.m., except Saturdays, when the time will be from 10 a.m. till 12 noon. Headquarters will be closed for all purposes on August 3rd and 4th.

### THE NEW GLASGOW POWER STATION

MR. W. W. LACKIE (City Electrical Engineer, Glasgow) has now completed the plans for the new power station, which is to have an ultimate capacity of 140,000 kw., and is to supplement the stations at Port Dundas and Pollokshaws Road, which are now loaded practically at their full capacity. An interesting feature of the system is that current will be transmitted from the works at a pressure of at least 20,000 volts, and probably 30,000 volts, to five distributing centres, which will include the existing stations at Govan and Partick, taken over by the Glasgow Corporation when these two Burghs were embodied in the City. At present, at any rate, the plant at these two stations will be retained and run in parallel with the new station at peak.

The new station, which is situated at Dalmarnock Bridge, on the Dalmarnock Road, will occupy a site of 53,677 sq. yds. The first section of the station to be built will contain one unit of 15,000-kw. capacity, and two units of 10,000-kw. capacity each. In view of the size of these units the boilers will, of course, have to be built at right-angles to the engine-room, and the boiler-house will be in three floors, as suggested in Mr. Lackie's remarks at the I.M.E.A. meeting, published in our issue of last week. A steam pressure of 200 lb. per sq. in. will be employed, and the steam will be superheated to 650° F. Water will be obtained from the Clyde, and a special canal is to be cut for this purpose. It

is estimated that there will be no difficulty in obtaining 10 million gallons of water per hour, which will be required when the station is working at its full capacity. A railway siding will, of course, be built on the site for the coal supply, and special arrangements are being made to enable a stock of from 60,000 to 70,000 tons being maintained if necessary.

It is proposed to generate current at 6,500 volts, and to step up to the 20,000 or 30,000 transmission voltage. As stated by Mr. Lackie at the I.M.E.A., the cost of the works is estimated not to exceed more than £10 per kw. of plant-capacity, and this £10 includes not only the power-house equipment, but also buildings, &c., although not the land.

### Conversazione of the Institution of Electrical Engineers.—

The Annual Conversazione of the Institution of Electrical Engineers was held at the Natural History Museum, South Kensington, on Thursday last, when a large number of members and visitors were received by Mr. W. Duddell, F.R.S. (President), and Mrs. John Smithers. Excellent programmes of music were performed by the String Band of the Royal Engineers in the main hall, and by the Royal Windsor Glee Singers in the Shell Gallery. Among those present were the following:—Sir F. A. Bosanquet, K.C.; Col. R. E. B. Crompton, C.B.; Sir William Crookes, P.R.S.; Sir J. M. Davidson; Mr. F. Gill; Mr. R. Hammond; Col. R. C. Hellard, C.B.; Col. Sir T. H. Holdich, K.C.M.G.; Prof. B. Hopkinson; Vice-Admiral Sir H. B. Jackson, K.C.B.; Prof. C. F. Jenkin; Dr. G. Kapp; Major J. N. C. Kennedy, R.E.; Mr. J. E. Kingsbury; Major-Gen. Beresford Lovett, C.B.; Prof. E. W. Marchant; Lt.-Col. The Hon. Sir N. J. Moore, K.C.M.G.; Mr. W. M. Mordey; Sir Henry Norman, M.P.; Dr. F. G. Ogilvie, C.B.; Major W. A. J. O'Meara, C.M.G.; Baron de Ropp; Mr. P. F. Rowell (Secretary); Major-Gen. R. M. Ruck, C.B.; Dr. A. Russell; Mr. A. H. Seabrook; Mr. Roger T. Smith; Mr. John Smithers; Sir John Snell; Prof. S. P. Thompson, F.R.S.; Prof. R. M. Walmsley; and Mr. W. B. Woodhouse.

### The Council of the Institution of Electrical Engineers.—

Mr. H. C. Levis (Managing Director, British Thomson-Houston Co., Ltd.) has been elected Associate member of the Council, to fill the vacancy caused by the death of Mr. A. Bruce Anderson.

THE HOT WEATHER.

A Suggestion for Seaside Electricity Works. A Daylight Summer Load with High Diversity Factor.

## MARCONI WIRELESS TELEGRAPH PATENT CASE

ON Wednesday last a case of considerable interest was opened before Mr. Justice Eve in the Chancery Division of the High Court of Justice. The plaintiffs were G. Marconi and Marconi's Wireless Telegraph Co., who sued the Helsby Wireless Telegraph Co. to obtain damages in respect of an alleged infringement of Marconi's Patent No. 7,777 of 1900 (now expired) by wireless apparatus which had been fitted on four ships, viz., *Anglia*, *Cambria*, *Scotia*, and *Umbria*, for the London & North Western Railway. Professor B. Hopkinson acted as assessor. Mr. A. J. Walter, K.C., and Mr. Hunter Gray (instructed by Messrs. Coward, Hawksley, Sons & Chance) appeared for the plaintiffs. Mr. Courtney Terrell and Mr. Arthur Jaffé (instructed by Messrs. Kenneth Brown, Baker, Baker & Co.) appeared for the defendants. The hearing of the case has been continued daily, with the exception of Saturday, and had not yet concluded yesterday.

The defendants denied infringement, and also claimed that the Patent 7,777/00 was invalid. Mr. A. J. Walter opened the case for the plaintiffs, and mentioned that, previous to 1900, investigators had found that a circuit which was a good conservator of electric energy was not well adapted for radiating electric waves, and *vice versa*. This difficulty was surmounted by Marconi's Patent of 1900, in which the transmitting apparatus consisted of two separate circuits tuned together. One circuit had a large capacity, and was therefore a good conservator of energy, and the other circuit, containing the aerial, was a good radiator. The two circuits were coupled through a transformer having a large leakage factor, i.e., "loosely" coupled. A similar pair of loosely coupled circuits were used at the receiving station. Fig. 1 shows the arrangement of the transmitting circuits.

Mr. Hunter Gray conducted the examination of the chief witness for the Marconi Co., Mr. J. Swinburne, who had examined the apparatus in use on the *Cambria*, and was of

FIG. 1.

FIG. 2.

opinion that it worked in accordance with Marconi's Patent. Mr. Courtney Terrell, in cross-examination of the witness, elicited the statement that in Marconi's apparatus, long trains of waves are supplied to the aerial, by the conserving circuit at the same rate as they are radiated. He then quoted some replies given by the witness in a previous case, to the effect that in Sir Oliver Lodge's Patent No. 11,575 of 1897, energy was poured into a good oscillator from a good conservator. Mr. Swinburne stated that Lodge's theory was that his aerial was charged by an "impulsive rush" of energy, whereas Marconi used long trains of waves. Resonance curves, constructed by Dr. Erskine Murray from the particulars given in 7,777 of 1900, were exhibited. These were seen to be double humped, thus showing interference between the primary and secondary circuits. A resonance curve from the *Scotia* was shown, and was seen to be a pure wave. This was said to be due to the fact that the sparks used were rapidly extinguished by the use of a charging coil, and two extra spark-gaps. Fig. 2 shows diagrammatically the arrangement of the circuits in the alleged infringing installations. Documents by Tesla, M. Ducretet, and Mr. Blondlot were cited as anticipatory to Marconi's invention.

Mr. Walter in re-examining Mr. Swinburne, quoted from a previous judgment by Mr. Justice Parker, a statement that Sir Oliver Lodge used two circuits for transmitting, so that the radiating circuit could be cut off from the supply circuit immediately after charging, not so that one acted as a reservoir for the other. The defendants' apparatus differed from Lodge's in having an extra inductance in the circuit, thus preventing the impulsive action desired by Lodge. Tuning was admitted to be well known before 1900 but it had not been suggested to use tuning and loose coupling for wireless

signalling. The second witness for the plaintiffs was Mr. Pletts, who in examination by Mr. Gray stated that in his opinion the calculations of Dr. Erskine Murray for the resonance curves previously shown, were incorrect owing to a wrong method having been used. The witness, in cross-examination by Mr. Terrell, admitted that Marconi's apparatus would give a "double humped" resonance curve. Re-examined by Mr. Gray, he said that he did not think that the small gaps and the charging coil, in the alleged infringing apparatus, were sufficient to quench the spark properly. Consequently he did not understand how the *Scotia* resonance curve was only single humped.

The next witness was Mr. Dugald Clerk, who was examined by Mr. Gray, and stated that he had examined the defendants' apparatus and found that they employed an autotransformer, and that the system was essentially similar to that used on the *Nonsuch*, and found to be an infringement (see ELECTRICAL ENGINEERING, December 15, 1910, p. 791), except that there were four spark-gaps instead of one, and that the transformer ratio was different. In cross-examination by Mr. Terrell, he admitted that a combination of an "Oudin" resonator with M. Ducretet's apparatus might have been successfully used as a Marconi transmitter. Mr. Walter, in re-examining witness, obtained a statement that M. Ducretet did not know how to utilise his apparatus for this purpose until Marconi's invention.

Mr. Terrell, in his opening speech for the defendants, said that the essential feature of Marconi's 1900 Patent was a persistently oscillating circuit, supplying energy to a good radiating circuit, i.e., the aerial circuit. The defendants' apparatus did not include a persistently oscillating circuit owing to the two small charging gaps which quenched the main spark very rapidly. With reference to the plea of invalidity he cited the writings of Tesla in 1898 and M. Ducretet, as containing the essential features of Marconi's Patent.

Dr. Erskine Murray, who was then examined by Mr. Jaffé for the defendants, contradicted statements by the previous witnesses that the small charging gaps and charging coil in the defendants' apparatus were inadequate to quench the main spark. In view of these conflicting opinions, the court took the opportunity on Tuesday of inspecting apparatus made by defendants to correspond with the *Scotia* installation. The main spark was viewed in a rotating mirror first with the charging gaps and coil in circuit, then with the gaps short-circuited and the coil cut out. A difference was observed between the two sparks.

The examination was continued yesterday, when witness exhibited a photograph of sparks from this apparatus. The cross-examination of Dr. Murray by Mr. Walter was proceeding on our going to press.

## A LONDON "BULK" SUPPLY AGREEMENT

THE Bill of the North Metropolitan Electric Power Co. which authorises the Power Co. to take a supply of electrical energy in bulk from the Metropolitan and London & North Western Railway Cos. was passed by a House of Commons Committee last week. There was considerable opposition on the part of the London County Council and the London supply companies on the ground that the proposed arrangement would tend to complicate the issue when the County Council came to purchase the London undertakings. It was pointed out to the Committee that the North Metropolitan Power Co. has authority to supply in one or two districts in the County of London by the permission of the local authorities, and that it is now actually supplying in Stoke Newington, and also to two small lengths of tramways. Eventually the Committee passed the Bill, with the proviso that any current taken from the two railway companies should not be used in the County of London other than in those districts where the Power Co. is at present giving a supply.

**Testimonial to Prof. John Perry.**—In view of the retirement of Prof. John Perry, F.R.S., from the staff of the Imperial College of Science and Technology, a fund is being raised to give expression to the appreciation of his services to Engineering Education. A part of the fund, which would be administered by the authorities of the Imperial College, would be devoted to a personal presentation, and a part to a prize to be awarded annually. A similar award may also be instituted at Finsbury. There must be many who wish to subscribe to the fund, including some outside the old students, who have already been appealed to. Subscriptions should be sent to the Hon. Treasurer, Mr. P. T. Wrigley, Royal College of Science, South Kensington, S.W.

## ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

### ELECTRICAL EQUIPMENT OF THE BLACKHALL COLLIERY

A PAPER by Messrs. J. J. Prest and J. Leggat, read at the London meeting of the Institution of Mining Engineers, described the sinking and equipment of the Blackhall Colliery, of the Horden Collieries, Ltd. Current for driving the electrical plant at this colliery is supplied by the Cleveland and Durham Electric Power Co., who already supply the Horden and Shotton Pits belonging to the same owners. At both of these, exhaust steam turbines are run in parallel with the power company's system. Electric driving, however, is used throughout the new Blackhall pit, and the plant includes two main electric winding engines, electrically-driven fans and air-compressors, motor-generators for the lighting circuits, electrically-driven underground pumps and haulages and surface machinery. The supply is at 2,900 volts three-phase 40 cycles, on which pressure all motors over 50 h.p. are run, and duplicate incoming feeders are provided. The smaller motors are run at 440 volts from two 200-k.v.a. Siemens transformers. All these are on the surface, for there is no motor of less than 100 h.p. underground.

The main winding engines were supplied by the British Westinghouse Co. They are both alike, and are designed to raise 189 tons per hour from 450 yards depth. Each cylindro-conical drum is given through 545 to 1 double helical Citroen gearing from a 700 to 1,500 h.p. induction motor running at a maximum speed of 230 r.p.m. No form of power storage is used, as the supply company are quite prepared to deal with the peaks of the load. These are believed to be the largest geared winding engines in the country. The gear runs in oil in oiltight cases. A very complete equipment of emerging and working brakes is provided fully interlocked with the control system, and worked from a motor-driven air compressor or alternately by the main compressed-air system as a stand-by. The controllers are of the liquid type, with fixed contact plates, and are worked by the electrolyte being pumped from one tank into another. The reversing switches, which are worked by the same lever that controls the liquid rotor resistance tanks, are oil-immersed with auxiliary sparking contacts.

The main switchgear is in two boards, each of the "ward-robe" type with steel cells. The bus-bars are sectionalised, and there are fifteen panels in all. The low-tension board is protected by Merz-Price gear, so that it is disconnected on any failure on the high-tension side. The two main air compressors are by Belliss & Morecom, and are direct driven by Westinghouse 535-b.h.p. motors running at 233 r.p.m. Each has a capacity of 3,000 cu. ft. of free air per minute compressed to 80 lb. per sq. in. There are two main ventilating Walker fans, one for 25,000 cu. ft. per min. at 4 in. water gauge, and the other 400,000 cu. ft. per min. at 8 in. water gauge. They are driven through ropes, and at their full speeds of 185 and 215 r.p.m. will require 300 and 800 h.p. respectively.

During the development of the colliery the fans will be run at varying speeds by changing the rope-pulleys. At the present time the small fan is operated by a motor of 100 brake horse-power, and the large fans by a 300 brake horse-power motor. Later on the 300 brake horse-power motor will be used for the small fan, and a bigger motor of 800 brake horse-power will be installed to drive the large fan, the 100 brake horse-power motor being then used for haulage purposes underground.

Two 60-kw. motor-generators, giving 220 volts D.C., are provided for both underground and surface lighting, including house and street lighting in the village. Each row of houses is provided with a pair of service-cables, running its full length in the false roof, to which cables the individual houses are connected. The ends of the service cables are brought out at the ends of the rows, and are then connected to the main bare stranded-copper distributors, which connect the rows together. No meters are installed in the houses, but each consumer pays a weekly amount according to the number of lamps installed.

The permanent underground pumping plant will consist of three high-lift Sulzer horizontal shaft turbine pumps each capable of pumping 1,500 gallons per minute against a head of 1,020 ft., direct driven at 1,170 r.p.m. of Westinghouse induction motors. The guaranteed over-all efficiency of these sets is 71.6 per cent. The underground haulages will be each driven by 100-h.p. 2,800-volt slip-ring motors with liquid starters, but these are not yet installed. Paper-insulated lead-covered cables are used throughout with the exception of the surface-lighting cables, which are carried overhead, and the power cables in-bye, which are paper-insulated, bitumen-sheathed, and double-wire armoured. The cables feeding the winding engines, workshops, and screens, and the portion of the shaft cables that runs between the switch-board and the shaft, are single-wire armoured, while the shaft cables themselves are double-wire armoured. All the cables on the surface are laid in sand, in specially built brick trenches. At the shaft-head the trench in which the shaft-cables are laid is enlarged into a chamber, in which a joint-box connects the surface portions of the cables to the shaft cables proper.

### GAS ENGINES FOR COLLIERY WORK

IN a Paper read at last month's London meeting of the Institution of Mining Engineers, Mr. J. Davidson dealt with the use of the internal combustion engine for power generation at collieries. Up till lately, he said, too little attention had been paid to the cost of power generation at collieries, but now there was a growing tendency to economise by using exhaust steam turbines. He dismissed this, however, as a makeshift, and insisted that the most economical prime mover of the present day was the internal combustion engine. The gas engine was admirably suited for colliery work. In cases where inferior coal is available it can be used most economically with gas-producers of the recovery type; and where the total power required is considerable, the return for the bye-products reduces the cost of gas to a negligible quantity. Where bye-product coke-ovens are in use, the surplus gas can be used to the greatest advantage in the gas engine; and, of course, for ironworks the most economical use for the blast-furnace gas is this form of prime mover.

Some comparative estimates were gone into for a 2,000-h.p. plant running 7,200 hours per annum, and the following costs per unit generated were arrived at. Steam turbine plant with coal-fired boiler, 0.238d.; steam plant with boilers fired by recovery producer gas, 0.244d.; gas engines with recovery producers, 0.141d., coke-oven gas fire boiler with steam turbines, 0.193d.; and coke-oven gas in gas engines, 0.126d. A further possibility in economy lay in the use of boilers heated by the exhaust from the gas engines, which could evaporate from 2½ to 2½ lb. of water per B.H.P.-hour.

Accumulated experience had now removed the reproach of unreliability from the gas engine. With the different kinds of gas it was now realised what cylinder compressions were safe from risk of pre-ignition. Statistics of break-downs showed that the gas engine now compared most favourably with the steam turbine. Going into engine details, the author expressed a preference for the vertical type of fairly high speed, which could be directly coupled to electric generators. There had been, however, a tendency to multiply the number of cylinders unduly, which was mainly due to a desire to avoid water-cooling of the pistons, although this was now quite practicable. He thought that the cross-head style of engine would supersede the single-acting trunk engine, and gave a description of the "Duplex" double-acting two-cycle engine now being built by Mather & Platt.

**A Possible Cause of Colliery Explosions.**—In the course of a speech at the annual dinner of the Institution of Mining Engineers, Prof. H. Louis referred to a Paper read recently by Mr. Rudge, in which he asserted that coal dust, carried along by a current of air, could become electrified, and was capable of charging insulated conductors to a high potential. He suggested that this might have been the cause of some hitherto unexplained explosions.

## ELECTRICAL PLANT IN A SOUTH WALES STEEL WORKS

ONE of the oldest firms in South Wales engaged in the steel and tin-plate trade recently brought its plant up to date by adopting electric drive for a considerable portion of the works. The power house contains two 230-kw. 500-volt 50-cycle steam-driven "Witton" three-phase alternators running at 428 r.p.m. These have direct-coupled exciters, which are also utilised for lighting. An interesting application of electric power in this works is the driving of the furnace pushers, illustrated here. They are driven by 50-h.p. "Witton" reversible intermittently rated motors geared to the pushers by spur-wheels and rack. One pusher serves for operating two rows of ingots. These it moves alternately. The cold ingots are placed in front of the pusher, which is advanced as soon as the furnace-door is opened, and the

ELECTRICALLY-DRIVEN FURNACE PUSHER.

ingots are forced by successive operations through the furnace. A large roll-turning lathe is driven by a direct-coupled 50-h.p. motor through worm gearing. It gives a turning speed on the lathe of 1.5 to 2 r.p.m. by means of a speed controller in the rotor circuit. The charging boxes for the steel furnaces are loaded by means of "Witton"-Kramer magnets. As the power generated is alternating current, the magnets, which are of 42 inches diameter, are supplied through motor-generators.

The magnets are suspended from a travelling crane. Within six months of the installation of the first magnet it was realised that very great economies were being effected, and a repeat order was placed for a similar equipment. The electrical equipment for this installation was supplied by the General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, E.C.).

**Electric Lamps for Mines.**—In the course of a Paper by Mr. A. D. Mitton read recently before the Manchester Geological and Mining Society, the author said that many mines were using electric lamps entirely, except for examination of the mine for gas. In a recent case where only electric lamps were used a man was overcome by gas, and died before its presence had been detected. The management at once ordered that in every working-place where electric lamps were used there must always be a spare flame lamp; but a few days afterwards a heavy blower of gas came out suddenly whilst work was in progress; the gas immediately extinguished the flame lamp, and the men just managed to escape with their lives by the light of the electric lamps.

**Ignition of Gas by Sparks.**—Referring to Prof. W. M. Thornton's experiments on the limiting voltages and currents below which the ignition of gaseous mixtures cannot be effected, Dr. J. Mennier writes to the *Colliery Guardian* stating that, according to researches by himself and Prof. Couriot, the size of the wires has considerable influence on the igniting power of the spark, fine wires enabling ignition to be effected with smaller currents. With silver wires 0.1 mm. diameter they ignited a mixture containing 9.5 per cent. of methane with an almost invisible spark.

### AN EXPLOSION-PROOF CIRCUIT-BREAKER.

TO meet the demand for a small explosion-proof circuit-breaker for mining work the General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, E.C.), have placed on the market the small breaker illustrated here. Its capacity is 30 amperes at 300 volts, or 15 amperes at 500 volts. It is of the double-pole type with overload trip. The case is explosion-proof, with wide and well-machined flanges, which are in no case cut away to take the holding-down bolts. A flame-proof gland is provided where the switch spindle passes through the case. Internally the device has

30-AMPERE FLAME-PROOF G.E.C. CIRCUIT-BREAKER.

been designed with ample clearance and with ample insulation. The G.E.C. standard patent interlock is embodied so that the breaker cannot be closed until the lid is first closed, nor can the lid be opened until the breaker is in the "off" position. This interlock has been specially designed for colliery work, for which interlocking gear of a delicate nature is entirely unsuitable. The overload trip is easily adjustable over a wide range. The breaker has been designed to take the G.E.C. standard mining glands, which complete the flame-proof characteristics of the case.

**The Association of Consulting Engineers.**—At the annual meeting on May 25th, the annual report and accounts were adopted on the motion of the chairman, Mr. G. Midgley Taylor, and the following were elected to fill vacancies on the committee:—Town members: H. W. Handcock, H. J. Rofo, A. M. Sillar, and M. G. Weekes; country members, J. H. Blizard and T. H. Yabbicom. The report gives the number of members as seventy. The Association has now been incorporated under the Companies Act. The necessary alterations to the articles have been made to admit membership of the Institution of Civil Engineers of Ireland as a qualification. The Association has been in communication with local authorities with a view to discouraging advertising for consulting engineers, and in relation to the offer of the electrical department of a certain borough to act as consulting engineers to mill and factory owners at a fee. The Committee of the Association announce that it is willing to undertake the appointment of umpires in engineering contracts.

**The Batti-Wallahs.**—The summer outing of the Batti-Wallahs, which took the form of an up-river trip on Saturday last, was a great success. About 90 members with ladies and friends participated, and the start was made on the launch *Royal Thames* at 2 o'clock from Kingston. The party proceeded up river to Weybridge, where a meal was provided, and returned to Kingston about 9 o'clock. Among those present may be mentioned the President, Mr. Avila, Mr. and Mrs. Snow Huddleston, Mr. and Mrs. F. Pooley (Hon. Sec.), Mr. and Mrs. Ashley Pope, Mr. and Mrs. Prangnell, Mr. and Mrs. Barfield, Mr. and Mrs. Wyld, Mr. Lange, Mr. and Mrs. Newton Russell, Mr. R. W. Hughman, Mr. and Mrs. Fisher, Mr. and Mrs. Sharp, Mr. and Mrs. Donison, and Mr. Ralph Ball. Mr. D'Arcy, of the B.T.-H. Co., contributed to the impromptu concert on board at the piano. A special number of the *Batti-Wallah's Journal* was published for the trip.

### LIFTING MAGNET TRANSPORTER EQUIPMENT

IN order to overcome the delays due to the trucks bringing the charging material for loading the charging boxes in steelworks, passing along one or two lines only, a wide span transporter crane is now often used. The accompanying illustration shows a good example. The Witton-Kramer magnet equipment shown is particularly effective, and accom-

TRANSPORTER EQUIPPED WITH LIFTING MAGNETS LOADING CHARGING BOXES FROM RAILWAY TRUCKS IN A STEEL WORKS.

plishes the unloading of trucks from any of the sets of rails. It was found that at the ordinary rate of working 58 tons of material could be fed into the charging boxes in 57 minutes—a remarkably good performance. The magnet is of 52-in. diameter, and was constructed by the Witton-Kramer Electric Tool & Hoist Co., Witton, for whom the General Electric Co., Ltd., of 67 Queen Victoria Street, E.C., are the sole selling agents.

### MINING AND METALLURGICAL PATENTS FOR JUNE

#### Mining.

IN specification 26,802, of 1913, J. Kraus describes an improved type of electrostatic separator in which the electrodes are made of a partially conducting material, such as wood, marble, or paper. The material to be separated is allowed to fall vertically between two or more charged electrodes, and any attracted material is conveyed away by endless conveyor bands, which pass over the surface of the electrodes. The chief advantage is that sparking between the electrodes is prevented.

#### Metallurgical.

The following specifications, which have been published during June, will be of interest to metallurgists:—No. 11,370, of 1913, communicated to the B.T.-H. Co. by the G.E. Co. of America, describes a method of manufacturing steel having a very low hysteresis loss by annealing silicon steel in an electric annealing oven. The process must be carried out under vacuum. A method of improving the purity of the metallic products of electrolysis by arranging a porous diaphragm between the two electrodes, so as to prevent the passage of impurities, forms the subject of specification No. 11,364, of 1913, by E. J. Hunt, of Oldbury. Another communication from the G.E. Co. of America to the B.T.-H. Co., describing a method of producing boron suboxide by heating a borate in contact with silicon in an electric furnace, is found in specification No. 15,757, of 1913. The improved manufacture of electrolytic iron by first oxidising the electrolyte by stirring in contact with air, and then using a rotating cathode, and increasing the temperature of the electrolyte during electrolysis, forms subject-matter for specification No. 16,565, of 1913, by Société Anon. "Le Fer," of Isère (France). W. N. Crafts, of Ohio, in his specification No. 18,073, of 1913, gives particulars of an induction shaft-furnace, in which the secondary circuit is formed entirely of metal instead of a mixture of slag and metal, as in previous types. He also shows an arrangement for allowing the molten metal to be tapped off without interfering with the electric continuity of the secondary circuit.

# QUESTIONS AND ANSWERS BY PRACTICAL MEN

## RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper, attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

## QUESTION No. 1,398.

A three-phase slip-ring motor generator, 400 h.p. 2,200 volts, is loaded about 35 per cent., and is supplied from a distant power station  $2\frac{1}{2}$  miles away, through aluminium lines 37/12 S.W.G. The motor runs satisfactorily until another motor of 300 h.p. is switched in circuit, when a heavy thump is heard shaking the foundation and breaking the bridge connections of rotor winding each time the second motor is switched in; this machine is controlled with reversing switch, and is 500 yds. further away. The thump is not heard in the motor when switching on the motor-generator. The starting current of the motor is about 50 amps. at 2,200 volts.

Can I do anything to prevent this heavy thump?—DEAD EARTH.

(Replies must be received not later than first post, July 9th.)

## ANSWERS TO No. 1,398.

The diagram represents a set of resistances connected up as a Wheatstone's bridge. Show how to calculate the combined

resistance between A and B, and the current that will flow through each arm of the circuit if a potential difference of 100 volts is applied between these points. "C. M. Y."

The first award (10s.) is given to "P. H. S." for the following reply:—

Let C and D (in Fig. 1) be the voltage at the points indicated, and let a, b, c, d, and e be the currents in the branches indicated.

By Kirchoff's law the algebraic sum of the currents at any

FIG. 1.

point is zero. Therefore currents at points C and D in the figure are zero, and the following simultaneous equation is obtained:—

$$\frac{100 - C}{5} - \frac{C}{20} - \frac{C - D}{5} = 0 \quad \therefore -9c + 4d = -400$$

and

$$\frac{100 - D}{20} + \frac{C - D}{5} - \frac{D}{5} = 0 \quad \therefore 4c - 9d = -100.$$

From this we get the values  $C = 61.54$  volts and  $D = 38.46$  volts.

$$\therefore \text{Current in } a = \frac{100 - C}{5} = \frac{100 - 61.54}{5} = 7.69 \text{ amps.}$$

$$b = \frac{C}{20} = \frac{61.54}{20} = 3.08 \text{ ,,}$$

$$c = \frac{C - D}{5} = \frac{61.54 - 38.46}{5} = 4.61 \text{ ,,}$$

$$d = \frac{100 - D}{20} = \frac{100 - 38.46}{20} = 3.08 \text{ ,,}$$

$$e = \frac{D}{5} = \frac{38.46}{5} = 7.69 \text{ ,,}$$

Total current flowing =  $a + d$  or  $b + e = 7.69 + 3.08 = 10.77$  amps.

$$\therefore \text{Combined Resistance} = \frac{E}{C} = \frac{100}{10.77} = 9.3 \text{ ohms.}$$

The second award (5s.) is made to "E. H.," who writes as follows:—

The simplest way to work out this problem is, first of all, to calculate the currents in each circuit, and then, from the total current, to determine the combined resistance of the arrangement.

Let  $I_1$ ,  $I_2$ , and  $I_3$  (Fig. 2) be respectively the currents in AC, AD, and DC, and that the directions of these currents be as indicated in the figure. Since the resistances are arranged:

FIG. 2.

symmetrically,  $I_1$  and  $I_2$  will also be the currents in DB and CB respectively. The pressure across AB is given as 100 volts. Now, it is quite immaterial which circuit between A and B we consider; the algebraic sum of the voltages between those two points must in each case be 100 volts. Thus, taking circuit ACB, we have

$$5I_1 + 20I_2 = 100, \quad \therefore I_1 + 4I_2 = 20 \quad (1)$$

Circuit ADB gives the same equation.

Again, taking circuit ACDB,

$$5I_1 - 5I_3 + 5I_1 = 100, \quad \therefore 2I_1 - I_3 = 20 \quad (2)$$

The reason for the -- sign is that the current  $I_3$  is being assumed to flow from D to C.

Also, from circuit ADCB, we have

$$20I_2 + 5I_1 + 20I_2 = 100, \quad \therefore 8I_2 + I_1 = 20 \quad (3)$$

Subtracting (2) from (3) gives

$$4I_2 - I_1 + I_3 = 0, \quad \therefore I_3 = I_1 - 4I_2 \quad (4)$$

If we consider the currents at, say, C, the sum of the currents flowing towards that point is equal to the sum flowing away from it.

$$\therefore I_1 + I_3 = I_2, \quad \therefore I_1 = I_2 - I_3 \quad (5)$$

From equations (4) and (5)

$$I_1 - 4I_2 = I_2 - I_1, \quad \therefore I_1 = \frac{5}{2}I_2$$

Substituting for  $I_1$  in equation (1), we have

$$I_2 = 20 \times \frac{2}{13} = 3.08 \text{ amperes}$$

$$\therefore I_1 = \frac{5}{2} \times 3.08 = 7.7 \text{ amperes.}$$

and  $I_3 = 3.08 - 7.7 = -4.62$  amperes.

i.e.,  $I_3$  actually flows from C to D, and equals 4.62 amperes.

(Value of  $I_3$  has been purposely arranged to be negative, to show that it is immaterial, in the above calculation, in which direction we assume it to flow, so long as equations (2) and (5) are written with the corresponding signs.)

Total current flowing in at A =  $I_1 + I_2$ , = 10.78 amperes.

Combined resistance of the whole arrangement

$$= \frac{\text{Volts across AB}}{\text{Total Current}} = \frac{100}{10.78} = 9.28 \text{ ohms.}$$

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published June 25th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad

12,421/13. **Manufacture of Tungsten.** C. GLADITZ. A method of obtaining tungsten in a form which is ductile and which has a comparatively high tensile strength. The finest form of tungsten-powder known, i.e., the "fluffy" form, is mixed with a certain percentage of a coarser-grained powder, compressed in a mould, and then gradually sintered in an atmosphere of inert gas. Precise information is given as to the method of making the coarser-grained powder from the fluffy form, as to the proportions of the two powders, and as to the exact way of carrying out the sintering process.

15,392/13. **Improved Mercury Rectifiers.** B.T.-H. Co. (*G.E. Co., U.S.A.*). The object of this invention is to prevent "reverse arcing" between the electrodes which normally act as the anodes. The anodes, which may be of any suitable metal such as iron or tungsten, are made hollow and filled with mercury, which is kept heated at its boiling point by independent heating coils immersed in the mercury. As the mercury is vaporised, it passes into a condensing chamber, and thence returns to the hollow interior of the anode. A method of sealing the anodes where they enter the rectifying chambers, so as to allow for adaption to changes of temperature without allowing any air to enter the evacuated interior of the rectifier is also contained in the specification. Four figures.

25,643/13. **Telephone Receiving Apparatus.** WESTERN ELECT. Co. (*R. Woodward*). An improved type of loud-speaking receiver, consisting of a metal casing which contains a double horseshoe magnet built up of four arms joined to a common yoke, a smaller electromagnet situated between the two poles of the composite magnet, and a sound-box containing a diaphragm to the centre of which is attached one end of a lever which is rigidly fixed to a flat armature situated near the poles of the above electromagnet. A set-screw is provided for varying the strength of the magnetic field by altering the air-gap between the electromagnet and its armature. It is claimed that its operation is very efficient. Five figures.

8,719/14. **Heating and Cooking Utensils.** R. SPRENGER. The invention relates chiefly to the hot-plate type of heaters. Hitherto, these plates have had to be made with comparatively thick walls in order to obtain a good accumulation of heat and to prevent the burning through of the heating elements which would occur if the tops of the plates were thin. Consequently the thermal efficiency of the plates has been small. By mounting the plate on a vertical spindle in the cooking range and arranging a powerful spring underneath, so as to force the plate up against the bottom of any utensil which may be required to be heated, it is possible to make the wall of the plate the desired thinness. Projections must be provided on the range and the utensils so that the latter remain in position. The connections are arranged so that the current cannot be switched on until the utensil is in position on the plate. Six figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** MARKS (*Siemens Schuckertwerke Ges.*) [Search-lights] 21,833/13.

**Dynamos, Motors and Transformers:** SOC. SCHNEIDER ET CIE. [Rotary transformers] 21,309/13; LANE [Dynamos] 253/14.

**Electrometallurgy and Electrochemistry:** MOSCICKI [Furnace for gas treatment] 13,250/13; WATIMANN AND TUDOR ACCUMULATOR Co. [Railway rail-joints] 14,519/13; COWPER-COLES [Deposition of copper on iron] 25,393/13.

**Heating and Cooking:** WEAVING and FERRANTI, LTD. [Water heaters] 9,930/13; MORDREY [Resistances] 15,764/13.

**Ignition:** UNTERBERG and HELMLE [Magneto apparatus] 13,006/13; TRIER [Engine starters] 16,965/13; TWIDDY & STALLY [Magnetos] 1,421/14.

**Instruments and Meters:** LEEDS [Resistance meter] 25,716/13; FARIES [Testing instruments] 26,997/13.

**Storage Batteries:** ICONOMUS [Accumulators] 22,841/13.

**Switchgear, Fuses and Fittings:** ROTHMAN and FERRANTI, LTD. [Motor starters] 12,936/13; NAYLOR and NAYLORGRAPH, LTD. [Devices for series lighting] 13,558/13; PERRY [Automatic motor-switches] 14,994/13; BRIT. WEST. ELECT. & MFG. Co. (*West. Elect. & Mfg. Co., U.S.A.*) [Circuit-breaker] 4,663/14; R. BOSCH [Regulators] 8,916/14; TURNER [Switches] 10,041/14.

**Telephony and Telegraphy:** COLONNA [Printing telegraphs] 18,568/12; HAMMOND [Wireless control apparatus] 13,310/13; MARCONI'S WIRELESS TELEGRAPH Co. and FRANKLIN [Wireless receivers] 13,636/13; [Means for increasing A.C. frequency] 13,637/13; SIEMENS & HALSKE AKT.-GES. [Selectors] 13,748/13; [Automatic telephone call meter] 6,892/14; ZEI and NARDIN [Relays] 18,438/13; EASTERN TELEGRAPH Co. and FRASER [Telegraph receivers and relays] 19,121/13, [Automatic telegraph transmitter] 26,278/13; GRAHAM [Telephone system] 27,753/13, 310/14; SOLDATENCOW [Telegraph receiver] 27,859/13.

**Traction:** MOUYEN [Signalling system] 10,803/13; MURRAY [Train control] 13,242/13, 13,243/13; SIEMENS BROS. & Co. and BOOT [Railway signalling] 25,018/13.

**Miscellaneous:** LEACH [Fans] 22,235/13; NITSCH [Alarms] 2,493/14; GRAHAM and SANTAFLEBEN [Telephone systems] 8,906/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** LIBANO [Insulator for overhead conductors] 12,443/14.

**Dynamos, Motors, and Transformers:** AKT.-GES., BROWN, BOVERI ET CIE. [Starting transformers] 12,012/14; SIEMENS SCHUCKERTWERKE-GES. [Slip-rings] 12,814/14.

**Switchgear, Fuses and Fittings:** DELLA CERDA [Lamp switches] 10,733/14.

**Telephony and Telegraphy:** DE LANGE [Thermo telephones] 4,203/14; HULTMANN [Telephone exchanges] 13,362/14.

### Application for Amendment

20,222/09. **Glass Reflectors, &c.** OTS A. MYGATT. Holophane, Ltd., seek leave to amend this specification on the ground that the scope of the patent as granted is too wide.

### Opposition to Grant of Patents

29,059/13. **Sparkling Plug.** C. SPADR. Opposition has been entered to grant of the above patent.

3,162/13. **Manufacture of Tungsten.** WESTINGHOUSE METALLFABRIK G. UHLAMPENFABRIK GES. It has been decided to allow the grant of this patent.

### Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

11,933/00. **Motor Control.** R. LUNDELL. A system of series-parallel control, chiefly applicable to motor-driven vehicles. The field windings of all the motors are connected in series, and a small motor generator is arranged to provide them with the necessary exciting current. The first three speeds are obtained by connecting all the motor armature in series and having different amounts of resistance in the generator field circuit of the exciter. The change from series to series-parallel, or parallel connections of the motor armatures, is effected without breaking the main field circuit so that sparking is partially avoided. The connections allow of regenerative braking being employed. A reversing switch for altering the main field connections is also included in the specification. One figure.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** E. S. ALI-COEN [Insulating compound] 5,279/08.

**Dynamos, Motors and Transformers:** G. W. MASCORD [Motors and controlling gear] 5,059/05.

**Electrochemistry and Electrometallurgy:** A. PETERSSON [Calcium carbide furnace] 5,658/07.

**Switchgear, Fuses and Fittings:** NALDER BROS. & THOMPSON and A. F. HARRIS [Circuit breaker] 5,073/05; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Lightning arresters] 5,575/06; A. E. WOODHOUSE [Metallic conduits] 6,010/06; R. F. VENNEN and R. C. GRIESBACH [Automatic switches] 18,583/09.

**Traction:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Railway signalling systems] 6,135/07, 6,134/07, 6,135/07. H. PIERER [Petrol-electric transmission system] 5,159/08, 5,160/08; SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*) [Railway signals] 5,698/08.

**Miscellaneous:** S. LEETHAM [Ozonising apparatus] 5,790/04; L. E. R. PHILLIPS [Musical instruments] 5,170/08; A. V. PRIOR [Clocks] 5,687/09; R. A. FESSENDEN [Utilising solar heat] 28,577/09.

### ANNOUNCEMENTS RELATING TO PATENTS.

*Small Prepaid Advertisements with regard to Patents, &c., are inserted on this page, facing our Patent Record, at 1d. per word (minimum 5s.); three insertions for the price of two. Rates for displayed, illustrated, and card advertisements on application.*

*Advertisement matter, accompanied by a remittance, should be addressed to the Kilowatt Publishing Co., Ltd., 203 Temple Chambers, London, E.C.*

The Proprietor of the Patents 15,991 of 1909 and 26,341 of 1911 for "An Improved ELECTRIC LOCKING and UNLOCKING DEVICE FOR LOCKS," and "Improvements in ELECTRIC LOCKING DEVICES FOR LOCKS," is desirous of entering into arrangements by way of license and otherwise on reasonable terms for the purpose of exploiting the same and ensuring their full development and practical working in this country. All communications to HASELTINE, LAKE & CO., Chartered Patent Agents and Consulting Engineers, 28 SOUTHAMPTON BUILDINGS, CHANCERY LANE, LONDON, W.C.

### G.E.C. CARBON WORKS

IN our issue of June 18th, 1914, a short account was given of the carbon works of the General Electric Co., which were open for inspection on the occasion of the I.M.E.A. visit to Wotton during the Convention. The illustration herewith will be recognised by those who visited this portion of

BAKING OVENS FOR ARC LAMP CARBONS.

the works as a view of the baking ovens, in which the rods are gradually heated up to the requisite temperature by being transferred from oven to oven, each succeeding oven being slightly hotter than the preceding one. When thoroughly baked, the rods are allowed to cool by being transferred gradually back to the coolest oven.

### ELECTRIC TRACTION NOTES

In the course of his Board of Trade Report on the collision which occurred at Burntisland on the North British Railway on April 14th last, Major Pringle calls attention to the fact that three of the coaches involved were lighted by gas and the remainder by electricity. On one of the former the gas caught fire, but owing to the position of the coach the flames were extinguished. The inspector writes that so much has been said in other recent cases upon the danger of the use of gas as an illuminant, that there is no need to write at length on this subject. "But I wish to point out," he continues, "that from my own examination I have no doubt that the origin of the fires in this case was burning gas, and that the gas jets from the undamaged cylinders, which were

not fitted with cut-off valves, appear to have burnt for a longer period than has sometimes been calculated."

The Highways Committee of the L.C.C. reports that the results of the 1913-14 year's working of the tramways show a deficit of £88,525, which is to be met out of the general reserve fund. This result is arrived at after the payment of £328,109 interest, and £408,488 repayment of capital. In a special report the Committee calls attention to the unfairness of motor-omnibus competition, and states that if the accounts of the Council's tramway undertaking were dealt with on a similar basis to those of the London General Omnibus Co., the result would be a return of 6½ per cent. on the capital expenditure. Figures are given, showing that whereas the tramway undertaking pays £187 10s. per tram-car towards public funds in the form of rates and taxes on track, licences and debt charges on contributions to street widenings, the Omnibus Co. only pays £37 4s. 6d. per 'bus. Special stress is laid on the fact that not only does the Omnibus Co. pay nothing towards road maintenance compared with the tramways undertaking, which is to a large extent maintaining the roadway for the benefit of its competitor, but that omnibuses also reap the advantage of street widenings towards which the tramway undertaking pay a large percentage. Steps are to be taken to improve the working of the tramways by linking-up the various lines and doing away as far as possible with dead ends.

The Aberdeen Suburban Tramway Co., which recently put into service several petrol-electric omnibuses, which travelled from London to Aberdeen under their own power, is shortly taking over another similar 'bus. An opportunity is to be afforded to any Aberdeen citizens to accompany the 'bus from London to Aberdeen should they desire to do so.

The Dundee Corporation has offered to purchase the Dundee, Broughty Ferry, and District Tramway Co. at £8,500. The Tramway Co., however, has asked for a sum of £15,486. Broughty Ferry was recently taken over by the Dundee Corporation under an Act of Parliament granted last year.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

At the annual meeting of the Marconi International Marine Communication Co. on Tuesday, Mr. G. Marconi presiding, a final dividend, making 10 per cent. for the year, was declared on the ordinary shares. The Chairman stated that it was a matter of great satisfaction that the Company was now soundly on its feet and earning reasonable dividends. Reference was made to the important part which the Company's installations have played in saving life at sea, whilst a complaint was made at the criticisms frequently levelled at the Company by Members of Parliament at its monopoly. Mr. Marconi, however, contended that nobody could assert that the Company had put its monopoly—if it possessed one—to an improper account.

Replying to several questions in the House of Commons last week with regard to the Imperial wireless telegraph scheme, Mr. Hobhouse said that several of the masts of the United Kingdom installation have been erected, and a considerable amount of material has been sent out to Egypt. Material was also on the point of being sent out to East Africa, India, and Singapore. The Post Office, however, was not at present in a position to undertake the work of erecting the three remaining stations. It was open to the Government, said Mr. Hobhouse, to cancel the contract with the Marconi Co. for these stations, and he was still prepared to consider the question of employing any other contractors who were able by means of practical demonstrations to satisfy him of the efficiency of their system.

Automatic telephone exchanges are apparently to be tried in Norway, as we learn that an automatic exchange is to be installed in Christiania at a cost of £55,000. The present number of subscribers in Christiania is 20,000 out of a population of 250,000.

On June 26th the Nagasaki-Tamsui cable failed, and a notification was issued stating that telegrams for Syria and Irak are no longer subject to delay.—The cable between Cayenne and Salinas was restored to working order on the 29th ult., and on June 30th, owing to an interruption between Constantinople and Angora, and between Constantinople and Konia, telegrams for Syria and Mesopotamia are being sent by a circuitous route involving delay.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 391. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**CHROMOLYTE BATTERIES.**—We have received from J. J. Eastick & Sons (Clapton Common, N.E.) a leaflet dealing with the "Chromolyte" primary batteries. These batteries, which are well adapted for use in hand-lamps, are said to possess several advantages over other types, amongst which may be mentioned high voltage, light weight, and ease of recharging. The electrolyte is made up in collapsible tubes, and may be conveniently stored in the lamp case until required. We are informed that no deterioration can occur, no matter how long these cells are kept in stock.

**"RAWLPLUGS."**—Revised prices of these useful plugs for enabling screws to be driven into any kind of wall are given in a leaflet from the Sun Electrical Co., Ltd. (118-120 Charing Cross Road, W.C.).

**IMMERSION HEATERS.**—A convenient hot-point immersion heater, pleasantly known as "El Boilo," is dealt with in a folder from R. W. Haylock & Son (63 Queen Victoria Street, E.C.). A number of other pieces of domestic electric heating apparatus are also listed.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**CONDUIT FITTINGS, &c.**—A leaflet from Electrical Conduits, Ltd. (18 Bennett's Hill, Birmingham), describes a convenient conduit box which can be used as a connection or ceiling-rose box or for switches or pendants. Particulars are also given of a new form of adjustable die stock for screwing conduit tube.

**HALF-WATT LAMPS FOR PHOTOGRAPHY.**—A booklet from the General Electric Co., Ltd. (67 Queen Victoria Street), deals with the use of half-watt lamps for photographic studio work, a purpose for which they are eminently suitable, and lists a number of forms of special fittings and reflectors designed for the purpose. Special attention is called to the advantage of these lamps for autochrome work, as the quality of the light permits of shorter exposures being given than with other artificial illuminants. For most ordinary portrait work one 3,000-c.p. half-watt lamp is ample, and permits of shorter exposures than the usual arm lamp equipment.

**GLOVER'S ALMANAC.**—W. T. Glover & Co., Ltd. (Traford Park, Manchester), have sent us a copy of their popular daily sheet wall calendar, which covers the year from July 1st, 1914, to June 30th, 1915. This is the thirteenth of the series, and well upholds the high reputation which it has established. Each sheet contains a literary extract or an illustration of an instructive or humorous nature, in both cases well chosen, and with a variety which adds interest to each successive day.

## "Prana" Die Castings

will lighten your costs very considerably.

They leave the dies in a finished, ready-

for-use state, accurate to a degree only obtainable (by other methods) by long and costly "micro-machining." In addition to this each one is an exact duplicate of all the others—and so all die cast parts are automatically interchangeable, but they must be "Prana."

**AERATORS Ltd., UPPER EDMONTON, N.**

### LIGHTING OF THE SALVATION ARMY CONGRESS HALL

THE lighting installation of the large temporary hall built by Humphrey's, Ltd., on the Aldwych site for the Congress of the Salvation Army was undertaken by Francis Polden & Co. (56 Cannon Street, E.C.), who decided on the use of half-watt Osram lamps. Two distinct services are led into the building through two switch-fuse distribution boards in the entrance hall, where all control is effected. One service is taken from the ordinary 200-volt lighting mains, and the other from the special theatre mains, also at 200 volts, of the Charing Cross, West End & City Electricity Supply Co., Ltd. It is arranged that alternate lamps throughout are on the same service, so that the chance of the building being put into darkness by failure of the supply is extremely remote. All the wiring above 20 ft. from the ground is carried on porcelain insulators well away from any woodwork and the

THE SALVATION ARMY CONGRESS HALL.

walls. The interior lighting is by means of twenty-four 50-volt 300-watt half-watt Osram lamps, giving approximately 600 c.p. each, including one in the entrance hall. These are all enclosed in G.E.C. polished brass special half-watt fittings with "Superlux" bowls and reflectors. For the outside lighting on the Strand front two 100-volt 500-watt half-watt Osram lamps, of approximately 1,000 c.p. each, are enclosed in "First Citizen" lanterns with "Superlux" globes. The back entrance is lighted by four 200-volt 60-watt Osram lamps in G.E.C. watertight fittings, and all the exit notices are illuminated by means of Osram lamps of similar power. Over the steps an effective display is made by means of a strip containing thirty-two Osram lamps. The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), supplied the Osram lamps and the fittings. Francis Polden & Co. designed and carried out the lighting, and have also been responsible for the design and complete installation of the lighting of the new Kingsway Hall and the Salvation Army Congress Hall at Clapton.

**Demonstration of Electric Vehicles at Richmond.**—A demonstration of electric vehicles was held by the Richmond (Surrey) Electric Light & Power Company on the 18th inst. in the premises adjacent to the supply station, where the Company have accommodation which allows of a large number of cars being charged. The charging, handling, and trial running of the vehicles was shown to a number of the visitors. The Company look forward to doing considerable business in this direction in view of the facilities they can offer, and are actively pushing the matter by demonstrations and general advertising.

**Spare Automobile Lamps.**—Conveniently arranged cases of spare metal filament motor-car lamps are now sold by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), and by the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street). The boxes are strongly made and the lamps well protected. The selection of lamps carried can, of course, be varied to suit individual needs, but a usual arrangement is two headlight lamps, two sidelight lamps, one tail or dashboard lamp, and such lamps of the festoon or tubular patterns as are employed for the interior lights.

## ELECTRIC FANS

A NEW list from Simplex Conduits, Ltd. (Birmingham and branches), gives particulars of the Company's line in electric fans, sewing-machine motors, small motor-generators for accumulator charging, polishing and buffing motors, and centrifugal fans. The range of fans includes all

SIMPLEX FAN.

the usual types, from a simple desk fan of 10-in. diameter up to fans with box-blades 4 ft. in diameter. Prices are as low as is compatible with high-class materials and workmanship, as is instanced by the convertible-type bracket fan illustrated herewith, which is listed at 43s. Copies of the catalogue in question can be had on application to any of the Company's branches.

## INDIRECT LIGHTING OF A BANDSTAND

WHAT is believed to be the first example of the application of indirect illumination to the lighting of a bandstand is illustrated here. The installation is at Coventry, and consists of a single composition bowl "Eye-Rest" fitting equipped with Mazda lamps and X-ray reflectors, suspended

BANDSTAND AT COVENTRY WITH INDIRECT LIGHTING.

from the centre of the white ceiling. The illumination is ideal for the purpose. It is brilliant, yet absolutely glareless, and of course there are no inconvenient shadows.

At night the appearance of the bandstand is at once attractive and restful, and the musicians find the illumination better than anything they have met with for reading their music. We are indebted to the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), for the illustration.

**Siemens' Outing.**—Messrs. Siemens' Tantalum and Wotan lamp manufacturing department (Dalston) held their annual outing on Saturday last, when over 400 employees travelled by special train to Hastings. As in previous years, the firm bore the cost of travelling, leaving the individual members of the party free to make their own arrangements as to catering and entertainment. Mr. A. M. Hicks acted as secretary, and Mr. Le Marechal, Works Manager, accompanied the party, and in conjunction with the secretary spared no effort to ensure for those present a most enjoyable day's outing.

# Over 5,000,000 Carbon Lamps are in use to-day in Great Britain

The total current consumed by these carbon lamps represents, at a low price per unit, over £2,000 per hour of use.

Equal light can be obtained from MAZDA, OSRAM and WOTAN lamps at a cost of £500 per lighting hour.

MAZDA, OSRAM and WOTAN lamps, by reason of their sturdy drawn wire filaments, can be used wherever carbon lamps are used, and the consumer, while losing nothing in Durability, gains greatly in Economy and Brilliancy.

The profit to the Dealer on MAZDA, OSRAM and WOTAN lamps greatly exceeds the profit on carbon lamps.

## DRAWN WIRE LAMPS

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Aylesbury.**—Lighting and power switchboard, battery accumulators, mains, house-services, &c. Consulting Engineers, Kincaid, Waller, Manville, and Dawson, St. Stephen's House, Victoria Embankment, S.W. July 6th.

**Blackrock.**—Underground and overhead mains, feeder pillars, and public lighting. Consulting Engineer, J. P. Tierney, 15 College Green, Dublin. July 13th.

**Colwyn Bay.**—A new power-station at an estimated cost of £25,000 is to be constructed under the supervision of Mr. E. M. Lacey.

**Crook.**—Negotiations are being carried on with the Newcastle-on-Tyne Electric Supply Co. for a supply of electrical energy.

**Eastbourne.**—A Local Government Board inquiry was held last week concerning a loan of £4,656 for extensions to the generating plant.

**Gellygaer.**—The Council is inviting offers from consulting electrical engineers for the lighting of the district.

**Glasgow.**—First section of new Corporation Electricity Works, 35,000 kw.

**London: Hammersmith.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £15,500 for coal-storage tanks and transporting plant at the electricity works.

**Hampstead.**—A loan of £17,300, to meet the estimated capital expenditure during the year 1914-15, is to be applied for.

**St. Marylebone.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £5,524 for a 1,000-kw. converter and motor-driven centrifugal pump, &c., at the electricity works.

**Redditch.**—A Local Government Board inquiry is to be held on Tuesday concerning a loan of £18,000 for the extension scheme referred to recently in our columns.

**Truro.**—An application is to be made to the L.G.B. for sanction to a loan of £10,000 for the electric lighting scheme which Dr. Purves has prepared. Tenders are invited by July 4th for a suction gas plant equipment, together with mains, &c.

**Walsall.**—A Local Government Board inquiry was held last week concerning a loan of £74,850 in connection with the new power scheme which has been prepared by Mr. E. M. Lacey.

Four water-tube boilers with superheaters, economisers, and stokers; feed pumps and feed water heater; water softener, tanks, &c.; steam and exhaust pipes, &c. Consulting Engineer, E. M. Lacey, 12 Victoria Street, S.W. July 14th.

**Warrington.**—High- and low-tension cable. Borough Electrical Engineer. July 8th.

**Willesden.**—The Guardians are considering the question of taking a supply from the Council or putting down their own generating plant.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Barrow-in-Furness.**—Contracts have been let for elementary schools.

**Croydon.**—Two hundred and eight houses. Norbury Avenue. Chesterton & Sons, 52-3 Cheapside, E.C.—Eighteen houses, Addiscombe Avenue. J. Weller, Dalmally Road.—Eleven houses. Ashburton Avenue. Paish, Tyler & Crump, 5 Station Road.

**Gloucester.**—School. Education Committee.

**Kidderminster.**—New public baths.

**Margate.**—Wiring of the Queen's bandstand and grounds. Manager.

**Manchester.**—Rebuilding premises in Dickinson Street after fire.

**Oldham.**—New mill. Belgrave Mills, Ltd.

**Rochdale.**—Cinematograph theatre, Yorkshire Street.

**Southampton.**—School. Education Committee.

**Swansea.**—School. Education Committee.

**Wigan.**—Cinematograph theatre. Eagle Picturedromes, Ltd.—New school at Pemberton.

### Miscellaneous

**Willesden.**—Flame arc lamps are to be substituted for the open type lamps in a number of streets.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Belfast.**—The tender of the British Westinghouse Co. for a 1,000-kw. rotary-converter has been accepted at £2,003.

**Devonport.**—A contract has been placed with the B.T.-H. Co. for a twelve months' supply of C.C. mercury ampere-hour meters.

**Wallasey.**—Messrs. Chamberlain & Hookham have received a contract for A.C. meters.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £62 5s. to £62 15s. (Last week, £63 5s. to £63 15s.)

**Branch Manager.**—Bruce Peebles & Co. have appointed Mr. E. W. Browne as their Birmingham office manager, in place of Mr. Hilton, who has resigned. Mr. Browne has been connected with Bruce Peebles & Co. for many years.

**Change of Address.**—The United States Metallic Packing Co., Ltd., have removed their London office to 116 Fenchurch Street, E.C.

**Plant for Sale.**—The Leeds Electric Lighting Department has for sale, four Lancashire boilers, a water-tube boiler, a Green's economiser, three 1,000 I.H.P. and a 500 I.H.P. Bellis & Morcom engines, a 800-kw. E.C.C. generator, and other plant.

**New Edison Showrooms.**—The new City showrooms of the Edison & Swan United Electric Light Co., Ltd., at 123-125 Queen Victoria Street, were opened yesterday. They are conveniently arranged, and in an excellent situation. We hope to publish a description of them in an early issue.

## APPOINTMENTS AND PERSONAL NOTES

Those of our readers who know Mr. E. Barralet, of Messrs. Pinchin, Johnson & Co., will regret to hear that he was taken seriously ill towards the end of last week, and has had to undergo an operation for appendicitis. On inquiry at his house yesterday, we were informed that he is making good progress.

At a meeting of the Council of the British Electrical and Allied Manufacturers' Association last week, Mr. F. R. Davenport, managing director of Willans & Robinson, Ltd., was elected to the office of Chairman of the Council, recently rendered vacant by the death of Mr. A. Bruce Anderson.

Mr. W. Dundas, already on the staff of the Manchester Corporation Electricity Department, has been appointed Resident Engineer at the Dickinson Street and Bloom Street stations, in succession to Mr. F. H. Whysall, who was recently appointed Chief Electrical Engineer to the Greenock Corporation. Messrs. E. Atkinson and J. H. Niven have been appointed Shift Engineers.

At the last meeting of the Keighley Town Council a recommendation to increase the salary of the Borough Electrical Engineer from £300 to £400 was negatived. An amendment that the increase should be £25 was finally passed, after the voting had first resulted in a tie.

The salary of Mr. J. W. Hadfield, Borough Electrical Engineer at Barnstaple, is to be increased from £200 to £225 per annum.

Mr. N. H. Barker, of Fulham, has been appointed Technical Assistant and Testing Engineer in the Stoke-on-Trent Electricity Department, at a salary of £140 per annum.

A junior used to common battery switchboard maintenance is required at Hull. (See advertisement on another page.)

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

## LOCAL NOTES

**Belfast: Report upon Electricity Undertaking.**—Sir John Snell, who has been asked to report upon the general position of the electricity undertaking, in conjunction with Mr. W. J. Pratten, formerly Manager of the Engineering Department of Messrs. Harland & Woolf, has prepared an interim report dealing with the necessity for installing additional plant, in order to carry the undertaking over next winter's load. It is in connection with this report that the recommendation to purchase a 1,000-kw. rotary-converter, referred to in our "Tenders Received and Accepted" column, has been made.

**Brighton: Increased Heating Output.**—In reporting a net profit of £2,342 on the past year's working of the electricity undertaking, as against £1,407 in the previous twelve months, Mr. John Christie, the Borough Electrical Engineer, states that there has been a substantial increase in the supply for cooking and heating, &c. The above result has been arrived at in spite of an increase 3½d. per ton in the price of coal. The quantity of coal consumed, however, has been reduced by further economies in the operation of the generating plant. An improved system of lighting the front is recommended, by which Mr. Christie anticipates doubling the illumination without materially increasing the cost.

**Bury: Progress of Electric Supply.**—Mr. S. J. Watson, the Borough Electrical Engineer, calls attention in his annual report to the fact that during the year no less than twenty-four factory chimneys have been put out of use by the adoption of electric power, and that fifty-one chimneys have now been put out of use altogether in a similar manner.

**Chester: Electricity Profits and Relief of Rates.**—Of the sum of £4,941 net profit from the electricity undertaking last year, £500 are to be allocated to relief of rates and £1,094 to meet the deficiency on the lamp rate. The balance is to be transferred to the reserve fund.

**Eastbourne: Electric Cooking and Heating.**—Mr. J. K. Brydges, the Borough Electrical Engineer, in his annual report, reminds the Council that electric cooking and heating in Eastbourne cannot progress under the present rate of 1½d. per unit, notwithstanding the fact that there has been some increase during the past year. This, however, has been mainly due to the only large cooking outfit connected to the mains being in use for the whole of the year, as compared with only six months during the previous year.

**Ely: Gas Co. Refused Electricity Powers.**—The Ely Gas and Electricity Co. recently applied for an electric lighting Provisional Order for this district, but the Board of Trade has refused to grant it.

**Exeter: Electricity Profits.**—The past year's working of the electricity undertaking shows a net profit of £1,446. It is proposed to deal with this surplus by granting a discount of 15 per cent. to the Lighting Committee, and reducing the charge for current to the tramways from 1½d. to 1¼d. per unit. The balance is to be used towards providing a new high-pressure turbo-alternator.

**Hull: Development in Bulk Supply.**—Quite a feature of the past year's working of the Hull Electricity Department has been the number of bulk-supplies asked for which involve substations on consumers' premises. These range from 650-kw. to 4,000-kw. capacity.

**Ipswich: Electricity Profits.**—There was a net profit of £1,351 upon the electricity undertaking last year, compared with a deficit of £74 in the previous twelve months. In that year, however, the results were abnormally affected by the coal strike, and the inefficient conditions of working incidental to the installation of the new plant. From the balance this year the sum of £904 is to be taken towards meeting capital expenditure, and the balance is to be carried to reserve and renewals fund.

**London: St. Marylebone: Electricity Accounts.**—The quantity of electrical energy sold last year, viz., 17,038,516 units, shows an increase of 2,036,229 over the previous twelve months. The average receipt per unit, however, has still further gone down from 3d. to 2-73d. per unit. After meeting capital charges amounting to £115,914, there is a net surplus of £4,525, compared with £4,014 in the previous twelve months. The effect of the new arrangements with regard to the Sales and Publicity Department has been to slightly reduce the salaries, and Mr. Seabrook expresses the opinion that the new arrangement will work satisfactorily when it comes into full operation. With regard to the new 3,000-kw. Oerlikon generating sets, the contract was that these would carry an overload of from 10 to 15 per cent. After the order was

placed, however, the contractors voluntarily agreed to an overload up to 4,200 kw. for six hours, whilst since the machines have been at work the normal load has been increased from 3,000 to 3,500 kw. each, and the plant is actually being run at loads as high as 4,700 to 4,800 kw. Similarly, the guarantee figure of steam consumption was 13¼ lb. per unit, but this has now been reduced to 11-8 lb. Reference is also made in the report to the extensive use of electricity for heating and cooking purposes, and in this connection Mr. Seabrook states that the owners of a certain block of flats are installing electric heating exclusively in the bedrooms, as it has been found that this form of heating is cheaper than most other forms. An entirely new source of revenue has also been tapped during the last six months by the installation of hot-water heaters.

**Salford: Cheaper Lighting Tariff.**—A proposal has been made by the Electricity Committee to reduce the charge for lighting to 3½d. per unit in Salford, and 4d. per unit in Prestwich.

• **Southport: Electricity Committee and Contractors.**—Considerable controversy is taking place between the local electrical contractors and the Corporation Electricity Department in connection with the proposal of the latter to open a showroom, and to deal with cookers and heating apparatus on hire. The contention of the Corporation is that the contractors have never made a move in this matter, and are not able to do so, and that the proposal will in no way interfere with the business which the contractors have carried on hitherto.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Coalite.**—At the annual general meeting of this company last week, reference was made to the low temperature system of carbonisation for the production of gas, and it was suggested that by the use of this for the production of electrical energy, the fuel cost in generating stations in this country could be reduced to something like 0-08d. or 0-07d. per unit as compared with the present cost of 0-25d. per unit.

**Otis Elevator Co.**—A circular announcing the amalgamation of the Otis Elevator Co. with R. Waygood & Co. has now been sent to the shareholders of both companies. The extensions of the Waygood factory in London will be carried out as speedily as possible, and it is intended to evolve one type of elevator apparatus which will comprise all that experience has shown to be best from the previous working of both companies.

**Trafford Power and Light Supply.**—After transferring £3,000 to depreciation, the net profit for last year amounted to £4,846. In reference to the proposal of the Manchester Corporation to purchase the company which was refused by Parliament, the directors state it is reasonable to anticipate that an offer of purchase in the near future may be received from some other source.

**J. G. White & Co.**—Mr. J. B. White, presiding at the annual meeting on Monday, said that the Company's principal field of action had been during the past few years in South America. The net profit for the year was £70,387, which was slightly smaller than in the two preceding years, but these results the directors were satisfied with having regard to the conditions of trade generally. The directors are asking for increased borrowing powers.

**Aron Meter Co.**—The annual meeting was held on Tuesday, Mr. H. Hirst presiding. Although the net profits for the year are £4,000 less than those of the previous year, the Company has done a larger business in Germany, England, and France. The business, however, in Austria-Hungary has suffered adversely to the extent of £8,000. The conditions there, however, have now resumed a normal position, and there is every prospect of the Company's business as a whole continuing to show satisfactory results.

**Witton Works Outing.**—On Saturday morning last over 600 of the employees from the Witton works of the General Electric Co., Ltd., travelled by special train to Bournemouth on the occasion of the annual works outing. Owing to the difficulty of finding accommodation for lunching so large a party, the largest skating rink in the town was required. Lunch and tea were partaken of here under the chairmanship of Dr. Railing.

**Electrical Installations Outing.**—The seventh annual outing of Electrical Installations, Ltd., took place on Saturday, June 20th. One section of the party travelled by char-a-banc to Hastings, and the other by train to Southend-on-Sea. The weather was all that could be desired, and both parties appeared to have had a very enjoyable time.

## SUMMARY

AN illustrated article describes the latest forms of the aluminium electrolytic lightning arrester for high-tension line protection. (Page 394.)

A MOTOR generator installation for giving three-phase to special consumers from a D.-C. station is described. (Page 394.)

THE report of the Board of Trade Committee on explosions in connection with the use of bitumen in the laying of cables finds that such accidents have only occurred with separate single-core continuous-current cables. While not recommending the total discontinuance of laying cables solid in bitumen, in such cases they advise that each cable should be laid in a separate trough, and that other precautions be observed. (Page 395.)

THE wiremen's strike in London practically no longer exists. A note indicating the present position appears on page 395.

THE localisation of a particular kind of fault on a three-core cable is dealt with in our Questions and Answers columns. (Page 396.)

AMONGST the specifications published last week was one by Marconi's Wireless Telegraph Co. describing a method of increasing the frequency of electrical oscillations.—Application has been made for the restoration of a patent for improved switches.—M. I. Pupin's patent for the loading of telephone transmission wires expires this week, after a life of fourteen years. (Page 397.)

OUR Telephony and Telegraphy columns open with a description of the Carnarvon transatlantic wireless station. (Page 398.)

WE are now able to give details of the experiments of Colin and Jeance on wireless telephony. (Page 398.)

THE Marconi-Helsby Wireless Patent case was continued until Thursday last, when it was adjourned until Monday, July 13th. Evidence as to the persistence of the primary sparks in the defendants' apparatus was given. (Page 399.)

MR. OLIVER HEAVISIDE's Civil List pension has been increased, and Heaviside's work and the expiry of the Pupin "loading coil" patent are commented upon. (Page 399.)

THE Betulander Automatic Telephone Co. has developed an entirely new automatic exchange system in which relays entirely take the place of the usual electro-mechanical devices. (Page 399.)

THE first electric train for the L. and S.W. Rly. is now ready. (Page 399.)

IT is expected that the action of the Ilford Gas Co. against the Ilford Urban District Council with regard to supplying electrical fittings, and also alleging preferential terms in the matter of charging, will come on for hearing early next sittings. We suggest that the I.M.E.A. should take action in the matter. (Page 400.)

OUR Trade Section contains particulars of a new compact form of automatic cut-out for accumulator circuits. A new form of accumulator of light weight is also described. (Page 401.)

CABLE is required at West Bromwich; sub-station equipment at Hornsey; electrically-driven sludge pump at Ramsbottom; a 500-kw. rotary converter with transformers and switchgear at York; and large quantities of telephone apparatus in Australia.—An electric lighting scheme is under consideration at Criccieth. (Page 403.)

MR. J. H. BOWDEN, Borough Electrical Engineer, Poplar, complains of the revised list of repayment periods recently issued by the L.C.C.—Bulk supply agreements have been entered into between the Woolwich Borough Council, the South Metropolitan Electric Light & Power Co., and the West Kent Electric Co.—The Hackney Council has refused to appoint representatives to a proposed Committee of Borough Councils to investigate the question of bulk supply. (Page 404.)

THE reconstructed Crompton & Co. has had a successful first year.—The Consolidated Diesel Engine Manufacturers, Ltd., is to be wound up.—Edmundsons' Electricity Corporation show a satisfactory result of £23,125 last year, an increase of £4,225.—Some interesting information was given by the Chairman of the General Electric Company, at the Annual General Meeting last Friday, with regard to the satisfactory expansion of the Company's business. (Page 404.)

THE Robin Electric Lamp Co. is applying for a compulsory license to manufacture tungsten filament lamps and the application is to be resisted by the patentees. (Page 404.)

## ALUMINIUM LIGHTNING ARRESTERS

A RECENTLY issued pamphlet describes the latest forms of aluminium or "electrolytic" lightning arrester for high-tension alternating-current circuits supplied by the British Thomson-Houston Co. (Rugby). These are suitable for all potentials from 1,000 volts upwards, and one of their most important features is their two-fold discharge capacity. They have a discharge capacity limited by a series resistance sufficient for normal disturbances, and in reserve a large capacity limited ultimately by the resistance of the electrolyte. The principle of operation depends on the property of a film of aluminium hydroxide on the surface of two aluminium plates composing the cell, which, if in contact with a suitable electrolyte, have the characteristic of taking exceedingly small currents up to certain critical voltage, above which the current is only limited by the internal resistance of the electrolyte. The film is not broken down by this rush of current, but re-establishes its property of resisting the passage of current immediately. The critical voltage per cell is in the neighbourhood of 350 volts. In order to keep the cells in good condition, and to enable a low resistance electrolyte to be used, a horn gap is usually used in series, but as the protective film slowly dissolves when unconnected to the system, provision is made for connecting the cells directly to the system for a few seconds daily to re-form the film.

The construction of such an arrester, which consists of a series of inverted cones one above another in a tank of oil,

SECTION OF ALUMINIUM LIGHTNING ARRESTER.

is shown in the illustration. The cones are insulated from one another except for the electrolyte, while the oil prevents the evaporation of the solution. Four stacks of cones are provided, connected together at a common point, three of them being connected to the lines, and the fourth to earth. This system ensures the provision of an adequate number of cones to withstand conditions arising on one line becoming earthed, without requiring the provision of an excessive number of cones between lines. In arresters for circuits of 1,000 to 7,250 volts all the cones for the three phases are placed in one tank, but above 7,250 volts a separate tank is supplied for each stack. In order to limit the current which flows into the arrester during the period of charging and during the time of breaking the arc, the horn gaps are constructed with an auxiliary horn and resistance mounted above, and insulated from, the regular horns, so as to intercept the arc if it arises on the latter. Sufficient resistance is connected in series with the auxiliary horn always to limit the current and arc across the gap to a moderate value. Thus light discharges will pass across the smaller gap to the auxiliary horn and through the series resistance to the cells, but if the discharge is heavy the resistance offers sufficient impedance to cause the spark to pass to the main horn. This is accomplished with only a slight increase in potential because the gap is already ionised. If the cells are in normal condition the spark at the gap is immediately extinguished

without any flow of dynamic current. A transfer switch is provided for interchanging the earth stack with one of the line stacks during charging, so that the films of all the cells will be formed to the same extent.

## MOTOR-GENERATORS AT OLDHAM

THOUGH generating low-tension continuous-current power, the Oldham Corporation was recently called upon to supply three-phase energy to a consumer. For this purpose, and also in connection with three-phase turbo-generators which it was proposed to install in the power-house, the two 500-kw. 6,600-volt 50-cycle synchronous motor-generators running at 500 r.p.m. seen in Fig. 1, were laid down. The continuous-current generators have a voltage range of 410/520 volts, and are provided with separate exciters

FIG. 1.—MOTOR GENERATORS AT OLDHAM ELECTRICITY WORKS.

carried on an extension of the shaft at the alternating-current end. Owing to space limitations the machines had to be very compactly designed. The sets are started from the continuous-current side by liquid starters. After they are run up to speed and synchronised, the liquid starters are short-circuited. The starters, although situated in the basement, are actuated from the engine-room floor by a handwheel on a pillar, on which is also mounted the short-circuiting switch. The short-circuiting switch and the starter are interlocked, so that the former can only be closed with the switch in the "on" position. The interlocking device is

FIG. 2.—STARTER CONTROL PILLAR.

shown in Fig. 2. The rotation of the handwheel raises or lowers the small catch seen above the upper contact of the switch. With the catch down, which corresponds to an open position of the liquid starter, the switch cannot be closed. If the switch is pulled out, the catch rises to enable this to be done, but flies back to a position from which it obstructs the switch if any attempt be made to replace it. The motor-generators and switchgear were supplied by the General Electric Co., Ltd., of Witton, Birmingham, and 67 Queen Victoria Street, London, E.C.

## ELECTRIC MAINS EXPLOSIONS

THE report of the Departmental Committee on Mains Explosions appointed by the Board of Trade to consider the causes of explosions which have occurred in connection with the use of bitumen in laying cables at Nottingham, Hebburn, and elsewhere, has now been issued. The Committee consisted of Sir T. E. Thorpe, F.R.S. (Chairman), Mr. R. Nelson, Mr. W. Slingo, Mr. J. Swinburne, and Mr. A. P. Trotter, with Mr. M. J. Collins as Secretary. A number of witnesses, including several engineers of large electricity undertakings, were examined.

During the past eleven years six or seven explosions due to vapour generated by short circuits on cables have taken place in houses, and a number in the streets. On investigation it was found that none of these occurred on alternating current by concentric or three-core cables or lead-covered, paper-insulated cables. "There remain," continues the report, "the class of single-core, separately-laid cables, insulated with india-rubber or with vulcanised bitumen. Although at one time vulcanised rubber cables of excellent quality were made, and it appears might still be made at a higher price, inferior qualities have given trouble. . . Vulcanised bitumen has been the material used for insulating the cables in all the cases of serious explosions in houses, and these have been drawn into bitumen casing, or laid in bitumen on the solid system." It is remarked, however, that the manufacture of bitumen casing has practically ceased.

In discussing the various causes of deterioration of bitumen, it is stated that it is softened by contact with coal-gas, but no case of explosion has been traced to this cause. A fault on a positive cable produces corrosion and eventual interruption of the copper conductor, but a fault on a negative decomposes the insulating material, and not the conductor, and moisture is attracted by osmosis, causing the bitumen to become pulpy. When the resistance of the cables is sufficient to control the current, the heat may only melt the surrounding bitumen, causing it to flow in and quench the arc. If, however, the arc persists, the vulcanised bitumen and the bitumen in which the cables are laid is melted. Both vapour and gas are driven off. At the high temperature which is present the vapour is "cracked", or dissociated into gas in considerable volume, and if in a confined space, under considerable pressure. When these products can force their way and escape through the surface of the roadway or between the joints of paving stones there is a chance that the arc may burn itself out, either by flooding of bitumen or by failure of current consequent on the lengthening of the arc owing to melting and volatilisation of the copper. If owing to an impervious pavement the gas is forced, or if having free access it passes into a house and becomes ignited, an explosion may be the result.

The immunity of alternating circuits may be due to their smaller size, or to the absence of osmotic action, and it is suggested that the absence of such accidents in three-core and concentric cables is due to the more serious nature of a short-circuit, resulting in better protective systems in such cases, and the necessarily higher class of jointing. In the solid system bitumen and pitch-compound are the only practical filling materials. The latter is cheaper, and has a lower melting point, and is apparently not affected by creosote or by coal-gas. "While more gas is given off on heating pitch than on heating bitumen, only two minor explosions of street boxes have been recorded where pitch has been used, and it must be remembered that street-box explosions are often due to the sudden expansion of air by the heat of a heavy short-circuit." There appeared from the evidence to be considerable difference of opinion regarding the best material for troughs.

"It appears," continues the report, "that a condition precedent for a serious explosion is to be found where two or three separate vulcanised bitumen cables are laid solid in bitumen in one trough. The experience of breakdowns has led to certain improvements in carrying out the solid system, and where conditions are such that lead-covered, paper-insulated cables or armoured cables laid direct in the ground cannot be recommended, the solid system carefully laid with due precautions has its advantages, but it ceases to be a cheap method. Earthenware troughs with separate chases or a separate trough for each cable is the best method, but it is expensive and occupies a good deal of space." In some cases accidents may have been due to breakdown of service-joints, but there is some difference of opinion among the witnesses on this point. The Hebburn accident was due to three preventable causes. At a corner where the direction changed 40°, wooden troughs were merely mitred together:—(a) Not only had the

two cables been pulled up against the wood, but the outer one had been pulled until it rode over the other, and so remained for eleven years, when a fault developed. (b) An impervious continuous cement pavement was laid over the cables. (c) The cables were laid close to the foundations of a house and these consisted of loose rubble with no lime or cement. In most cases where explosions have occurred an impervious pavement of concrete or asphalt had been laid over the mains. It is found that with a flagged pavement the gas can escape between the joints. In three cases of explosions services have been so laid that access was given to the interior of houses, and gas freely entered. Most witnesses agree that services should be solidly bricked in, armoured cable being generally preferred. There was general agreement that services should not be carried in on the solid system. After discussing at some length the testing of cable networks for insulation, and their fusing and division into districts, the final conclusions of the Committee are given as follows:—

The Committee finds that the explosions to which its attention has been directed have occurred in connection with electric supply by continuous current through separate cables, for the most part insulated with vulcanised bitumen and either drawn into bitumen casing or laid solid in troughs filled with bitumen.

The Committee finds that no serious explosions have occurred where the supply has been by alternating current, or where concentric or three-core, or lead-covered paper-insulated cables have been used, or where cables have been laid solid in pitch-compound; but a direct comparison between bitumen and pitch-compound cannot be made as the former material has been more extensively used than the latter.

In view of the small number of serious accidents which have occurred, compared with the large extent to which vulcanised bitumen cables laid in solid bitumen have been used, the Committee is unable to recommend the Board of Trade to discontinue to approve of this system.

In view of conflicting opinions of witnesses the Committee cannot recommend that iron or stoneware troughing should be used to the exclusion of wood, but they recommend that wood troughing should be used only where it can be ascertained that the soil is suitable; that where separate mains are laid in troughing each cable should be laid in a separate trough, and that between the troughs there should be a space not less than 2 in. tightly packed with earth or sand.

The Committee recommends (1) that separate mains for continuous-current supply should not be laid on the solid system below impervious pavements or close to the walls of houses; (2) that easy bends should be laid at corners, and the bitumen or pitch-compound should be poured after the straight lengths have cooled; (3) that where sharp corners of troughing are suspected to exist the mains should be opened up and the corners eased; (4) services should be taken into houses (preferably by the use of armoured cables) in such a manner that gas cannot enter.

The Committee also recommends that the special attention of engineers of electric supply undertakings should be called to Section 38 of the schedule to the Electric Lighting (Clauses) Act, 1899, and to No. 12 of the Regulations made by the Board of Trade for securing the safety of the public, which require notification of accidents by explosion or fire, or any other accident of such kind as to have caused, or to be likely to have caused, loss of life or personal injury which have occurred at any part of any electric line or work, in order that the circumstances may be investigated, and, when necessary, reports made on them.

The Committee is strongly of opinion that such reports should be published for the information of those concerned.

In an appendix is given the report of Dr. R. V. Wheeler of the Home Office Experimental Station, Eskmeals, on the gases evolved from bitumen on a pitch at different temperatures, and showing their high degree of inflammability. The separate reports of Mr. A. P. Trotter (Electrical Adviser to the Board of Trade) on the explosions in Hamilton Place, Piccadilly, and Pall Mall in 1908, in Battersea Park Road in 1909, in the Strand and in Nottingham in 1911, and at Hebburn in 1913, are also printed at the end of the report, which can be obtained from Wyman & Sons, at the price of 8d.

**The Wiremen's Strike in London.**—This strike may now be regarded as a thing of the past. The minimum wages of 10½d. per hour for wiremen duly came into force on July 1st in accordance with the working rules of the London Electrical Masters' Association, and we learn that as many men are to be had by the various firms as are required. The jobs are practically divided into those on which union men work and on which non-union men work, and in some cases, we believe, both union and non-union men are employed by the same firms, but not on the same jobs. The amount of work is, however, still very limited in consequence of the continuance of the builders' strike.

## QUESTIONS AND ANSWERS

### BY PRACTICAL MEN

#### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

#### QUESTION No. 1,399.

A Hartmann & Braun hot wire voltmeter is used on A.C., and has a scale of 0-250 volts. It is desired to use this instrument for a range of 0-500 volts by multiplying present scale by two. How can this be accomplished?—METER.

(Replies must be received not later than first post, Thursday, July 16th).

#### ANSWER to No. 1,397.

A fault occurs on a 7/16 3-core paper, lead-covered and armoured cable 300 yds. long, laid direct. On testing, it is found that each core has gone to earth, and also burnt clear from the remaining portion of the cable. Two-thirds of the cable is in the middle of a road at a depth of 3 to 5 feet, the remainder under paving-stone in the pathway. State the most reliable test for locating this fault to avoid opening up as much as possible.—ADSUM.

Although several replies have been received, none appears to us to meet the circumstances of the case with sufficient completeness and practical detail, and no award is therefore made.

The procedure we should recommend is as follows:—

Adsum's description of the case is represented by Fig. 1 or Fig. 2; it is, of course, not known whether the fault has occurred in the part of the cable under the roadway or under the pavement. It is to be assumed from his description that the conductors are burnt clear both from themselves and earth at the side beyond the fault.

Send a gang to open the pavement at A.

While this is being done, measure the resistance between the ends marked 1 & 2, 2 & 3, and 1 & 3. If this is greater than 0.65 ohm, which is the resistance of two cores for the full length of 300 yards, it is no good proceeding further with resistance measurements, as the resistance of the fault is greater than that of the cable. On the other hand, if the three measurements are under 0.65 ohm and are steady and all practically identical, it is possible that the three conductors are well fused together at the fault, and, as a first approximation therefore the distance of the fault may be taken to be

$\frac{2 \times 0.001086}{0.001086}$  yards (0.001086 ohm is the resistance of 7/16 cable per yd. at 60° F.). It may be taken for granted that the distance of the fault from the station is not greater than this.

If the engineer is a quick worker, he will probably have made this test and have had time to survey the spot indicated before the footpath at A is open and the cable ready to cut. If his inspection of the spot indicated by his calculation gives no clue as to the fault being near there, he should proceed to cut the cable at A, and test each way. He will then see at which side of A the fault is, and have the conditions either of Fig. 3 or Fig. 4. If the conditions are as shown in Fig. 3, he should take a capacity measurement on the known length AB, and then another towards the fault on the length AF, and the distance of the fault from A will be in proportion to the capacity.

If the conditions are as in Fig. 4, a capacity measurement

on the known length AC should be taken, and another from the end B towards the fault, and the distance of the fault from B will be in proportion to the capacity.

In taking these capacity measurements, connect all three

cores together, earth to the lead of the cable for a few seconds to discharge the cable, and then take a capacity swing, in the usual way, on charging with a battery between the bunched cores and the lead of the cable through a galvanometer. If it is possible to use the same battery and galvanometer under precisely the same conditions for the two tests, it is only necessary to compare the swings, as these may be taken as approximately proportional to the capacity.

If it has been possible to take a useful resistance test as mentioned in the first instance, compare the result of this with the result of the capacity test, and take the result which gives the fault nearer to the station end for the reason already indicated.

#### Conversazione of the Institution of Civil Engineers.—

The Conversazione last Thursday of the Institution of Civil Engineers was the first that has been held in the handsome new building in Great George Street, which proved sufficiently commodious to accommodate comfortably the 3,000 guests that were received by the President, Mr. A. G. Lyster. The interest of the evening was added to by the very fine collection of engineering models and instruments on view in the reading rooms and other rooms on the ground-floor. Among these specimens of historic submarine telegraph cables were shown by Mr. Charles Bright, and a number of pieces of wireless telegraph apparatus were exhibited by Capt. H. R. Sankey and Marconi's Wireless Telegraph Co. These included a demonstration of the new wireless distant-control apparatus used for controlling fog signals (referred to in another part of this issue), a large collection of instruments, and a model showing the method of construction of high steel masts. Other interesting exhibits were working models of the old Betulander and Post Office automatic telephone systems. Messrs. Waygood & Co. showed a working model electric lift. Miners' electric safety lamps were shown by Mr. H. F. Joel, and samples of corrugated rails from the L.C.C. Tramway system by Mr. A. L. C. Fell. The musical portion of the programme included songs by Miss Agnes Nicholls to the accompaniment of the string band of the Royal Engineers. The Westminster Singers and Mr. Percy Godfrey's English String Sextet also contributed to the enjoyment of the evening.

**Complimentary Dinner to Sir John Snell.**—A general desire has been expressed that the honour of Knighthood recently conferred upon Sir John F. C. Snell, President-Elect of the Institution of Electrical Engineers, should be made the occasion of a complimentary dinner in the early autumn, and a Committee is in course of formation to make the necessary arrangements. Those wishing to associate themselves with the event are requested to send their names as soon as possible to any one of the following:—P. F. Rowell, The Institution of Electrical Engineers, Victoria Embankment; D. N. Dunlop, British Electrical & Allied Manufacturers' Association, King's House, Kingsway, W.C.; A. H. Dykes, Association of Consulting Engineers, 11 Victoria Street, S.W.; H. Faraday Proctor, Incorporated Municipal Electrical Association, The Exchange, Corn Street, Bristol; L. G. Tate, Electrical Contractors' Association, 20 Bucklersbury, E.C.

**Works Outing.**—The employees of the Western Electric Co. to the number of over 150 travelled by special boat and special train to Clacton-on-Sea on Saturday, June 27th, on the occasion of their annual outing. A sports meeting was held on the Clacton Football Ground.

**A Fatal Joke.**—A curious electrical fatality is reported in the *Times*. A high-tension transmission line near Potsdam had broken, and the line ends were lying on the ground, when ten workmen seeking to "amuse themselves with electric shocks," joined hands and picked up the wires. All were thrown to the ground, and five were killed on the spot.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published July 2nd, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

9,930/13. **Water Heaters.** R. WEAVING and FERRANTI, LTD. An improved type of heater for household use, enabling small quantities of hot water to be drawn off in a short time, with only a small heat loading, larger quantities being available after a longer time. The heater is provided with an inner container of small capacity, in which the heating element is arranged. The water in the inner container heats up rapidly, and in expanding overflows into the body of the heater, so that a slow circulation is set up. Two taps are provided, one for drawing very hot water directly from the inner container, the other for cooler water from the body of the heater. Eight figures.

13,006/13. **Ignition Apparatus.** UNTERBERG & HELMLE. This invention describes the construction of a magneto, yielding an e.m.f. curve having several small peaks instead of one comparatively large and pointed peak. One projecting edge of each of the two pole shoes is perforated by a number of closely set drilled holes which give the edge a grid-like formation. Two figures.

13,637/13. **Frequency Increasing Apparatus.** MARCONI'S WIRELESS TELEGRAPH CO., LTD., and C. S. FRANKLIN. The source of A.C. current of which it is desired to increase the frequency is connected in series with a rectifier and a polarising direct voltage of requisite strength, which may be in the same direction as, or opposed to, that half of the current which normally passes through the rectifier. The rectified current is led through the primary of a suitable transformer, having a secondary connected to a capacity, and tuned to have a time period equal to half that of the original voltage. The frequency of the induced voltage in the secondary will then be double the original frequency. By using two or more transformers with primary and secondary circuits suitably arranged, higher transformation ratios can be obtained. During working, the battery which is used to supply the polarising voltage may become charged, and the surplus energy can be utilised to help to drive the alternator through a motor. The apparatus is, of course, particularly adapted for producing high-frequency oscillations for wireless signalling. Four figures.

25,018/13. **Railway Signalling System.** SIEMENS BROS. & Co. and J. BOOR. A system in which a battery of moderate size is made to supply an alternating or pulsating current, by means of a vibratory converter of the well-known type, to the insulated rails of a block section. The primary terminals of a transformer are connected across the rails at the other end of the section. The secondary winding of the transformer is connected in series with the operating coil of track relay. The tongue of this relay is in circuit with the coil of a second slow-acting relay, which controls the local circuit for operating the signals. When no train is on the section, the first and second relays are both closed, and the signals are kept in the required positions. When a train enters the section, the primary of the transformer is short-circuited, so that the first relay opens and allows the second relay to open after a short time. Any stray direct current, such as a leak from the traction circuit, cannot get beyond the transformer primary. The momentarily large fluctuation which may occur in the secondary due to such current would not be persistent enough to allow the second relay to close. Two figures.

25,393/13. **Copper-plating of Iron and Steel.** S. O. COWPER COLES. The iron or steel is thoroughly cleaned by pickling or sand-blasting, washed in running water, and dipped into a concentrated solution of nitric acid. When the evolution of gas ceases, the metal is again washed in running water and transferred to an electro copper depositing tank. The connection of the anode and cathode must be made before the steel is immersed in the electrolyte, which consists of a solution of potassium cyanide and copper sulphite in water. When the steel has received a good coating of copper, it is washed in hot water and transferred to a copper sulphate depositing tank, where the deposition is continued to any desired extent.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 3d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** SIEMENS SCHUCKERTWERKE GES., 9,960/14.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** WATERS [Reverse power relays] 13,418/13; FRANKUM [Insulators] 29,839/13.

**Dynamos, Motors, and Transformers:** FYNN [Dynamo-electric machines] 11,214/13; ARNO [Transformers] 11,539/13; WHITE-SIDE [Motors] 18,178/13; VON LEPEL [High-frequency transformers] 3,171/14.

**Electrometallurgy and Electrochemistry:** SCHULTE [Electroplating] 743/14.

**Ignition:** SCHUBERT [Magneto] 13,983/13; R. BOSCH [Interrupter] 10,683/14.

**Incandescent Lamps:** GRANN [Metallic filament lamps] 26,713/13; BLOCH [Filament support] 2,025/14; ELLINGER [Portable lamps] 5,024/14.

**Switchgear, Fuses, and Fittings:** HOPE [Blow-out apparatus] 9,109/13; SANDYCROFT, LTD., and DUTTON [Controller gear] 14,043/13; B.T.H. Co. (*G.E. Co., U.S.A.*) [Couplings] 15,074/13; TYLER, FREEMAN, and SHREWSBURY [Watertight switch] 17,761/13; HART [Switch control] 1,982/14; LUTLEY [Lamp fittings] 7,165/14.

**Telephony and Telegraphy:** WILSON [Production of h.t. discharges] 13,755/13; SIEMENS BROS. & Co. and PETTITHORY [Number dial for automatic systems] 14,614/13; CARTER [Telephone arm] 15,607/13; SIEMENS & HALSKE ART.-GES. [Automatic telephone systems] 22,850/13; SCHIESSLER [Wireless telegraphy and telephony] 29,447/13; FLEIJEL and OLSSON [Loading of telephone lines] 8,185/14.

**Miscellaneous:** SCOTT [Clocks] 13,715/13; DFARLE [Signalling apparatus] 23,478/13; GIRARDELLI [Distant control of guns] 198/14; AUB [Electric baths] 6,093/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos, Motors, and Transformers:** A.E.G. [Insulation of winding coils] 14,044/14.

**Storage Batteries:** R. BOSCH [Terminal connections] 7,686/14.

**Telephony and Telegraphy:** THORNBLAD [Train telephony] 13,854/14; BIENVAUX [Telegraphic code apparatus] 14,276/14.

**Traction:** CIE. GÉNÉRALE DES OMNIBUSES DE PARIS [Current collectors for tramways] 14,098/14.

**Miscellaneous:** CADENAL [Locks] 13,715/14; SIEMENS SCHUCKERTWERKE GES. [Machine tools] 14,021/14.

### Application for Restoration

27,196/03. **Improved Switches.** C. H. HUNTER. Application has been made for the restoration of the above Patent which expired in December, 1911, owing to non-payment of fee. Notice of opposition may be given on or before Sept. 1st, 1914.

### Opposition to Grant of Patents

13,282/12. **Manufacture of Ductile Tungsten.** Dr. P. SCHWARZKOPF, Dr. S. BURGSTALLER and WOLFRAM LAB. Dr. I. P. SCHWARZKOPF. An appeal has been lodged from the Comptroller's decision to allow the grant of this Patent.

25,606/12. **Time Limiting Device.** J. G. STATTER. The grant of this Patent has been allowed by the Law Officer.

### Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

12,733/00. **Reducing Attenuation of Electric Waves.** M. I. PUPIN. This specification relates to the loading of telephone transmission lines. The object is to enable impulses to be sent along the line with comparatively small currents, so that heat losses and therefore attenuation effects are minimised. Inductance coils are situated at equal intervals along the line, the exact number, and the self-induction of each coil depending upon the capacity and resistance per unit length of the line, and the maximum frequency of the impulses. A formula is given for determining the wave length of these impulses, and it is desirable though not essential, to allow 16 coils per wave length. Ordinarily no iron cores are required for the coils, but in the case of submarine cables, where it is necessary to enclose the coils in the sheathing of the cable, an annular laminated steel core is used for each coil. Twelve figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors and Transformers:** A. E. G. [Dynamo excitation] 6,312/09.

**Electrochemistry and Electrometallurgy:** E. CRUMIÈRE [Treating cellulose] 2,794/08.

**Incandescent Lamps:** H. T. GRAINGER [Annular lamps] 18,799/09.

**Telephony and Telegraphy:** G. W. PIERCE [Wireless telegraphy] 5,351/07; T. CLARK [Syphon recorder] 6,525/09.

**Traction:** ARMSTRONG, WHITWORTH & Co., and J. HONNER [Train lighting] 6,409/07.

**Miscellaneous:** J. GARDNER [Submarine signalling apparatus] 6,239/06; W. FAIRBURN-HART (*Electrolle Co.*) [Musical instruments] 5,728/08; H. LAKE (*G. Pino*) [Gripper for submarines] 6,164/09.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

### The Carnarvon Transatlantic Wireless Station.

The *Wireless World* contains a description of the new Marconi Transatlantic wireless stations near Carnarvon which have been recently opened. The transmitting and receiving stations are separate. The former is on the Cefn-du mountains, a few miles east of Carnarvon at a height of about 680 ft., and the receiving station to which it is connected by four land-lines is at Towyn, about sixty-two miles away. Such a long distance is not necessary, but was chosen owing to certain geographical features which allowed of the correct angular bearing of the stations. The transmitting station consists of a building about 83 by 100 ft. The main transmitting sets are in duplicate, each comprising a 300-k.v.a. single-phase alternator generating at 1,750 volts 150 cycles, and an exciter driven by a 500-B.H.P. 440-volt three-phase motor. The alternator is directly coupled to the rotary disc discharger, which is in a sound-proof room, by an insulating coupling, but an independent motor is provided so that the latter can be run asynchronously if required. The transformers, of 75 k.v.a. each, and the low-frequency inductances, are in a separate room with a complete equipment of safety and isolating switches. Although normally all operating is done from the receiving station, there is an emergency operating room, which also contains a master switch controlling the transformer safety switch, the receiving aerial isolating switch, the recovery crystal protecting switch, an illuminated sign "Ready to Transmit" in the shift engineer's office, and a disconnecting switch to the main earth lead. In an annexe is a considerable amount of auxiliary plant, including D.C. motor-generators, blowers, ventilating fans for the dischargers, &c. Practically all this plant is in duplicate. The condensers are arranged in tanks on two floors with the pots three in series. The "jigger" or oscillating transformer is of the independent primary and secondary type, and consists of a suitable number of turns of special H.F. cable wound on insulated frames which can be shifted axially to vary the coupling. Three aerial tuning inductances are provided. The aerial is of the directive type extending up the mountain side to a length of 3,600 ft., and averages 500 ft. in width. It is supported by ten tubular steel masts 400 ft. in height, and a ring of buried metal plates. Power is supplied at 10,000 volts three-phase by the North Wales Power Co.'s Cwm Dyli water-power station, eleven and a half miles away, and is stepped down to 440 volts in an adjoining sub-station. The receiving aerial at Towyn is supported by five masts, each 300 ft. high, erected on the hill at the back of the town, with the last mast about 1,400 ft. above sea-level. A balancing aerial is also provided to compensate for the effect of signals transmitted from Cefn-du, and this is carried on 80-ft. poles. The equipment can deal with 100 words per minute duplex. The signalling switches at the transmitting station are controlled from Towyn, where the punched tape from the Creed instrument is put through a Wheatstone transmitter, which by means of relays at Cefn-du actuates the signalling switches, making and breaking 300 kw. The station is in direct communication with the Company's headquarters at Fenchurch Street and Marconi House by direct landlines. The station with which Carnarvon is to communicate is at Belmar, New York. It is hoped that the equipment will also be able to be used for wireless telephony, and Mr. Godfrey Isaacs (Managing Director of the Marconi Co.) announced last week at a meeting of the Dominions Royal Commission that Mr. Marconi contemplated that directly he had made a few mechanical arrangements at Carnarvon, he would be able to telephone to New York.

### The Colin-Jeance System of Wireless Telephony.

Reference was made in *ELECTRICAL ENGINEERING* of June 18th, on page 384, to the overhearing by Mr. E. F. Blaze, at his station in Lincolnshire, of a conversation in Paris during experiments with the Colin-Jeance system of wireless telephony. We now hear through the Anglo-French Wireless Co., Ltd., from their affiliated Company, La Compagnie Générale de Radiotélégraphie, of Paris, that the telephonic messages in question emanated from their station at the Rue des Plantes, Paris, which has an antenna of only 164 ft. in height, and not from the Eiffel Tower as then stated. In view of the small aerial used, the result is even more remarkable. Through the courtesy of the Company we are now able to give some particulars of the Colin-Jeance system. The

continuous waves employed are produced by three arcs connected in series, each with a negative carbon electrode of 1.5 mm. in diameter, and a disc-shaped copper positive electrode which forms part of the base of a cylinder filled with paraffin and cooled by water circulation. The arcs burn in an atmosphere produced by mixing acetylene and hydrogen generated from calcium carbide and calcium hydride, respectively, in the same producer. This atmosphere prevents burn-

DIAGRAM OF CONNECTIONS.

ing of the carbon electrodes; in fact, they actually increase in length slightly. The arcs can be hand-controlled by separate regulators, but only very slight variation occurs. The supply voltage from the dynamo may be varied by shunt regulation from 500 to 750 volts, the current consumed varying from  $3\frac{1}{2}$  and  $4\frac{1}{2}$  amperes. From the diagram it will be seen that the current is led through choking coils and a steady adjustable resistance. The voltage at the terminals of the three arcs in series, where the oscillatory circuit is tapped off, is from 250 to 350 volts. When the oscillatory circuit is broken in passing from transmission to reception this voltage falls to approximately 150 volts, and a resistance is automatically inserted to compensate for this drop in voltage. The principal oscillatory circuit consists of an inductance and variable condenser, connected in parallel with the arcs A. An intermediate oscillatory circuit, B, consisting of an inductance and variable condenser is utilised to couple the principal circuit with the antenna, and ensures that multiple waves generated in the main circuit are not transmitted to the antenna, the result being that only a single wave is emitted. The antenna circuit consists of an inductance coupled with the circuit B and a variable condenser. A variable self-induction is also used in the aerial. The microphone circuit consists of nine carbon microphones connected in series and so arranged that they are all acted upon by the voice simultaneously by means of a megaphone. The microphones are connected between the variable inductance of the oscillation transformer and the earth, as shown at C. This has the double advantage of avoiding sparking, such as always occurs in the microphones when they are placed directly in the antenna, and does not limit the energy which can be taken by the microphones. The station has two complete microphone equipments, with a change-over switch, so that one can be allowed to cool while the other is in use. The station is also arranged for telegraphic transmission with a musical note, the pitch of which may be changed at will. The transmitting coils consist of flat spirals of copper strip, and the condensers are of the glass-plate type. Arrangements are provided for very exact tuning by means of variable air condensers. The wave-length of transmission can be varied between wide limits. In official tests a wave-length of 985 metres was used.

### Marconi Wireless Telegraph Patent Case.

The hearing of the case between Marconi's Wireless Telegraph Co. and the Helsby Wireless Telegraph Co. was continued until Thursday last, when it was adjourned until Monday, July 13th. It will be remembered that Dr. Murray, in course of examination by Mr. Jaffé, exhibited a spark photograph taken from the experimental apparatus. Under the conditions of the experiment witness had calculated that seven complete oscillations would occur before the amplitude had been reduced to one-tenth of its initial value. The photograph showed nine complete oscillations. The inference was that the spark photographs, which had been used in con-

structing some of the curves previously shown, could be taken as a fairly correct indication of the true nature of the spark.

In cross-examination by Mr. Walter, the witness was not prepared to deny that when cadmium electrodes were used for obtaining the spark, the oscillations were seen to persist for a much longer time than could be seen with copper electrodes. He admitted that, up to a certain point only, tightening the coupling of the two circuits increases the rapidity with which the energy is transferred from the primary to secondary. Mr. Walter drew attention to a statement given in Dr. Murray's "Handbook of Wireless Telegraphy," p. 243, 1911 Edition, that below 50 per cent. coupling the energy transference increases with increase of tightness of the coupling. Also that the energy transmission decreases with increase of the decrement of the primary circuit.

Mr. Terrell re-examined the witness who stated that he was still of opinion that defendant's apparatus did not contain a persistently oscillating primary.

Mr. Walter then recalled Mr. Pletts, who gave evidence of having conducted some experiments on an installation at Chelmsford, made to correspond with the alleged infringing apparatus. He inferred from these experiments that, under ordinary working conditions, there would be at least about 15 complete oscillations in each primary spark, so that in his opinion, the primary circuit was comparatively persistent.

After a brief re-examination of this witness by Mr. Terrell, the hearing was adjourned until Monday, July 13th.

### Oliver Heaviside: The Pupin Patent.

Telephone engineers will welcome the announcement that Mr. Oliver Heaviside's Civil List pension has been increased by £100. In 1896 Mr. Heaviside, who lives in retirement in the west of England, was granted a small pension, practically just sufficing for the necessities of life, and this increase is, at any rate, a recognition by the Government that the enormous developments in long-distance telephony and the economies in the cost of long-distance lines in recent years have been primarily due to his early work. It is an interesting coincidence that, in the same month as this announcement the Pupin patent, covering the use of distributed inductance in the form of coils in telephone lines, should be expiring, after a life of fourteen years, which must have brought large sums of money in royalties to the patentee. Pupin, both in his patent and writings, developed the fundamental doctrine enunciated by Heaviside, but practically unheeded years before, that distributed inductance in cables and lines must be beneficial to speech transmission. The patent, which, as mentioned in our Patent Record on another page, expires next Tuesday, gives itself an extremely clear exposition, aided by a mechanical analogy, of the function of the inductance, and gives clear calculations (with numerical examples) for determining how it should be inserted in the line. It was never contested during its life, although, so broad are the claims, that it practically covered any arrangement of inductance coils distributed in series throughout the length of a telephone line.

### New Automatic Telephone Exchange System.

We have been privileged to inspect a full-sized skeleton model of a new automatic telephone exchange system which may eventually revolutionise the present methods of automatic exchange construction. The Betulander Automatic Telephone Co., Ltd. (a Company affiliated with the Marconi Co., and with offices in Marconi House, Strand, W.C.), have taken up a new system which has been developed by Mr. Betulander, in conjunction with Mr. Palmgren, to supersede his ingenious automatic exchange which was only introduced a year ago.

SOME OF THE RELAYS.

In the new system all the connections and all operations are done by relays; there are no other electro-chemical devices. A series of "link lines," comparable in a way with the double cord circuits of a manual switchboard, or perhaps better with the vertical and horizontal bars of the original Edison peg switchboard, are allocated to each group of five

subscribers' lines; relays at the crossing points actuated by a group of relays called an "out-going searcher"—one of which is allocated to every 100 subscribers—connect to a free junction, and then the connections are made junction to junction by means of relays, and finally by an "incoming searcher" to incoming junction lines, and the link line of the called subscriber. The subscribers' lines are thus not multiplied at all, and the only multiplying in the ordinary sense is that of the junction lines, which are multiplied into

FRONT OF FIVE-SUBSCRIBER SECTION.

each group of five subscribers. The illustration above shows the front of one of the five-subscriber sections; the subscribers' line relays are at the bottom, and the junction wires enter at the top. The relays for all purposes do not differ materially in construction from ordinary relays; three different types are seen in the second illustration. The Company owns the patents of the system for all countries, except Sweden, and is now strongly staffed for its development work. It is under the leadership of Mr. C. B. Clay (late London Superintendent of the National Telephone Co.) and Mr. Arthur Williamson (late of the Western Electric Co.), and Mr. W. Aitken (late of the Automatic Telephone Mfg. Co.) joined the staff a few months ago as Technical Adviser. An actual exchange for Marconi House is to be the first constructed.

The Telephone Co. of Pernambuco, with a capital of £100,000, has been registered. The first directors have not yet been appointed, neither has the address of the registered office been filed.

Telegrams for Albania since the 1st inst. have been subject to great delay, and Tirana Elbassan, Kavaja, Shiak, and Pegin are entirely isolated, the wires having been cut.—The Ahvaz-Mohammerah line is down, and on the 6th inst. communication between Constantinople, Konia, and Angora was repaired.—One of the cables of the Pool Atlantic Cos. required attention of the ship recently, near the English shore.

### ELECTRIC TRACTION NOTES

We much regret that by an error the surface-contact tramways at Lincoln were referred to on page 331 of our issue of June 11th as being on the Dolter system. This should, of course, have been the "G. B." system. There are now no tramways at work in this country on the Dolter system.

The first of the new electric trains which have been constructed by the L. & S.W. Ry. at their Eastleigh works, consisting of a motor-coach and two trailers, is now complete, and is to be tested on the District Railway.

The promised capital reduction scheme of the British Electric Traction Co. has now been issued. It provides for writing down the capital by £908,372, and consolidating the four classes of stocks into two classes, viz., 6 per cent. cumulative preference stock and ordinary stock.

## GAS COMPANY'S ACTION AGAINST THE ILFORD ELECTRICITY DEPARTMENT

THE interesting action between the Ilford Gas Co. and the Ilford Urban District Council, with regard to the alleged illegal spending of money on electrical fittings, and also preferential charging, was mentioned in the Chancery Division before Mr. Justice Sargant on Friday. Mr. Mark Romer, K.C., who appears for the Gas Co., said that the Council had given an undertaking not to deal further in fittings until the action, and he had only to refer to the question of preferential charging. The point was, he said, that in December last the Council issued a new tariff intended to apply only to premises electrically lighted throughout, and this tariff, he contended, was a discrimination fully covered by his lordship's judgment in the Long Eaton case (ELECTRICAL ENGINEERING, May 14th, 1914, p. 266). This was a matter of argument rather than evidence, and in the circumstances he did not know what course Mr. Martelli, on behalf of the Council, proposed to take, having in view the difficulty at this time of the year of fixing an early trial for next sittings. The new scale came into force on January 1st.

Mr. Martelli, K.C., said he was prepared to continue his undertaking not to deal in fittings until the trial of the action, but with regard to the alleged preference, this, he argued, was certainly not within the Long Eaton judgment, which was a case of preference in charging as between the use of electricity for light and power. In this case the new tariff applied to consumers who at present use both electricity and gas for lighting, and was intended to induce them to use electricity solely for lighting, as by so doing they became better customers to the electricity undertaking. The new tariff did not interfere with the existing ones, and the con-

sumers still had the right to avail themselves of the existing tariffs.

Mr. Justice Sargant said it seemed to him that the damage done was that other consumers who did not use electricity absolutely would be placed in the position that their competitors in business would be trading upon more favourable terms.

Mr. Martelli said the Council alleged that the effect of the new tariff was precisely the same as the old, but that the new one was so framed that consumers could understand it very easily.

Mr. Justice Sargant said in the circumstances he did not think it was a matter he could dispose of on motion, and as the matter was not so very urgent, it could be left over until the trial next term.

This action, as well as the action against the Long Eaton Urban District Council, may be regarded as part of a campaign organised by the Gas Companies' Protection Association, which is a powerful body. It would certainly be advantageous if the I.M.E.A. were to take the matter up on behalf of the electricity undertakings, not necessarily to fight every action brought against an electricity department for alleged preferential charging, but to issue a clear definition to its members as to what is and is not preferential charging, and to fight those cases for them whenever there is an endeavour to attack the principle of this definition. Cases, on the other hand, in which Local Authorities without hiring powers have hired out motors, do not, we think, call for the intervention of the I.M.E.A.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 403. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**MOTOR-CAR ACCESSORIES.**—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), have issued a revised list of electrical accessories for motor-cars which includes coils for cars where battery ignition is still used, sparking plugs of the Lodge, Geeko, and other varieties, and a very full range of switches for ignition and car lighting circuits. Pocket and other voltmeters and ammeters for testing ignition and lighting cells are also listed, and a special feature of the list is the extensive range of interior lighting fittings. Head, side, and tail lamps are listed in various qualities, and complete lighting plants are represented by the C.A.V. and T. & M. systems. Batteries are dealt with in profusion, and mention should also be made of the motor-generators, switchboards, &c., for charging, and last but not least the latest type of Osram drawn wire lamps for motor-car lighting.

**LAMP HOLDERS, &c.**—A very large number of varieties of Edison screw lampholders, including many for special purposes, are listed in a catalogue of "P. & S." wiring devices manufactured by Pass & Seymour, of Solvay, N.Y., U.S.A.

**AIR COMPRESSORS.**—We have received from Alley & MacLellan, Ltd. (Sentinel Works, Polmadie, Glasgow), a fine, bound, illustrated catalogue of 160 pages giving particulars of air compressors of capacities from 25 to 25,000 cu. ft. of free air per minute, and containing a large amount of useful information regarding the uses of compressed air.

**ARC LAMPS AND ELECTRICAL PLANT.**—A conveniently arranged bound pocket catalogue from the Union Electric Co., Ltd. (Park Street, Southwark, S.E.), contains prices and particulars of complete ranges of arc lamps, dynamos and motors, switchgear and instruments.

**INSULATING TAPES.**—A leaflet from John MacLennan and Co. (30 Newgate Street, London, E.C.) deals with their various insulating tapes.

**WET AIR FILTERS.**—A leaflet from Ozonair, Ltd. (96 Victoria Street, S.W.), describes the system of cooling and washing large quantities of air which is used in connection with Ozonair ventilating plants, and is also applicable to the treatment of air for cooling turbo-generators.

**HIGH-PRESSURE SWITCHGEAR.**—A list from J. H. Holmes & Co. (Newcastle-on-Tyne) deals with oil break switches for switchboard mounting with automatic trip gear arranged in front of the panels.

### HALF-WATT LAMPS FOR SHOP LIGHTING

SIEMENS BROS. DYNAMO WORKS, Ltd., of Tyssen Street, Dalston, send us the photograph reproduced here showing the use of Wotan half-watt lamps at Williams & Thomas's stores, Broadway, Stratford. The photograph was taken entirely by the light of these lamps, which had been running for over three months without any breakages. The

HALF-WATT LAMPS IN THE CURTAIN DEPARTMENT OF A LARGE STORE.

lamps are of 1,000 c.p., and are contained in semi-indirect fittings with opal glass bowls, which give an even illumination without glare over a very wide area. We understand that these lamps, which have replaced small arcs, have given such satisfactory results that Messrs. Williams & Thomas have decided to place them in other parts of their stores where space warrants such a unit being used.

## A SMALL AUTOMATIC ACCUMULATOR CUT-OUT.

A NEW accumulator cut-out has been introduced by Nalder Bros. & Thompson (97A Dalston Lane, N.E.) to meet the demand for a smaller apparatus than the well-known Crawley pattern. This is known as the Beta midget automatic switch, and, like the Neville instrument, has a permanent magnet. This, however, is arranged so that it cannot be reversed; in fact, the action of the switch in use is to reinforce the magnet instead of reversing it. The apparatus is purely differential in its action, and is connected up in the manner indicated in the diagram. As in the original

FIG. 1.—FRONT VIEW OF A MIDGET ACCUMULATOR SWITCH.

FIG. 2.—SIDE VIEW OF SWITCH.

pattern of midget automatic battery switch, minimum weight is secured in the moving part, as the differential coil is wound on the same bobbin as the current coil, and not on the moving iron, consequently the mass to be moved is considerably less than is the case in some instruments which work in this manner. Compactness in design is secured by arranging for part of the instrument to be let in flush with the board, only that part of the mechanism carrying the mercury

cups and the dipper stands out on the front of the board. These are protected by a glazed polished brass case, which can be easily removed. This is a point of advantage, as instances have occurred, where skilled labour is not employed, that the dipper has been tampered with. Generally speaking, this instrument is only made for voltages up to 80 volts, and currents up to 50 to 60 amperes. The diameter of the hole which it is necessary to cut in the board is only  $5\frac{3}{8}$  in. This instrument is very compact, and is of neat appearance. The usual finish is polished brass, but nickelled or dull black cases can be supplied if required.

## THE PHOENIX ACCUMULATOR

A STORAGE battery embodying some interesting features is being introduced by Phoenix Accumulators (60 Wilson Street, Finsbury Square, E.C.). It is a lead-sulphuric acid battery, but, owing to the way in which the active material is supported, all possibility of buckling of plates, internal short-circuits, or falling-out of the lead oxides, is claimed to be prevented. The construction is shown in the section of one of the smaller sizes of cell given here.

CROSS-SECTION OF PHOENIX CELL.

The electrodes are tubular and concentric, and are composed of antimonial lead surrounded by the active material of finely granulated lead oxide retained by perforated tubes of slightly elastic material lined with flexible sheaths of a very porous material, and kept in position by india-rubber separating rings. The outer container is not perforated, and forms the wall of the cell. The electrolyte is able to circulate freely between the granules of active material, while a construction of considerable mechanical strength is obtained.

A special feature of the cell is the high proportion of active material which can be used, forming as much as 42 per cent. of the total weight, and the large effective surface in contact with the electrolyte. Consequently a very good weight-efficiency is obtained, amounting to 16.4 watt-hours per lb. of total weight, or 44 lb. per

FIG. 3.—DIAGRAM OF CONNECTIONS.

h.p.-hour output. A life of 300 charges and discharges is claimed to be obtainable without any deterioration. Phoenix cells are listed in various forms, from 6 to 120 ampere-hours, for ignition, motor-car, and train lighting, and other purposes where a light portable battery is required; and a miner's lamp fitted with one of these batteries is made, giving 2 c.p., and weighing 3 lb. 5 oz. We understand that traction batteries on this system have also been made.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Criccieth.**—The Lighting Committee recommends that the question of gas be entirely excluded from its investigations into the public lighting scheme, and that only electricity be considered.

**London: Hornsey.**—A Local Government Board inquiry has been held concerning a loan of £13,744 for the provision of a sub-station at Muswell Hill. One member of the public was present. The estimated cost of the plant is £9,394.

**West Bromwich.**—In order to meet some large new power contracts, additional cable, estimated to cost £2,080, is to be installed.

**York.**—A 500-kw. rotary-converter with transformers and switchgear. July 13th. City Electrical Engineer.

### Wiring

**Greenock.**—Electric wiring and fittings for Academy. Clerk, Municipal Buildings, Wallace Square. July 23rd.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Aberdeen.**—New training centre. Architect, J. A. Allan.

**Doncaster.**—Cinematograph theatre, St. Sepulchre Gate.

**Dudley.**—New municipal buildings.

**Honley.**—New municipal offices.

**Itchen.**—Isolation Hospital.

**London.**—Telephones, bells, &c., at Joyce Green Hospital, near Dartford, for Metropolitan Asylums Board. W. T. Hatch, Chief Engineer, Victoria Embankment.

New Theatre, St. Martin's Lane. Architect, W. G. R. Sprague.

**Lowestoft.**—New buildings and alterations to Town Hall. Borough Surveyor.

**Manchester.**—New factory, Dantzic Street. Architect, A. Sykes.—Warehouse, York Street. Architect, G. Westcott.—Warehouse, Charles Street. Architects, T. Cook & Sons.—Bank, Wilmslow Road. Architect, W. R. Sharp.—Cinematograph theatre, Coupland Street. Architects, Henderson & Brown.

**Newcastle-on-Tyne.**—New baths at Benwell, Walker, and Heaton. Surveyor, Town Hall.

**West Bromwich.**—Additions at Infectious Hospital.

### Miscellaneous

**Ramsbottom.**—Supply and erection of electrically-driven sludge pump with motor, wiring, counter-shafts, gearing, &c. James Diggle & Son, Hind Hill Street, Heywood.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Accrington.**—A contract has been entered into with the Chloride Electrical Storage Co. for maintaining the battery at the electricity works for eight and a half years at an annual charge of £166.

**Clones.**—The Board of Guardians has accepted the tender of the local electric lighting company at £50 for the lighting of the workhouse.

**Darlington.**—The following tenders have been accepted by the Electricity Committee: Water-tube boiler, Babcock & Wilcox; cooling tower, Balcke & Co.

**Edinburgh.**—The contract for the electrical installation at the Redford Cavalry Barracks has been placed with Lowdon Bros. of Edinburgh.

**London: Hammersmith.**—The tender of the British Electrical Transformer Co. for six 100-kw. transformers at £486, and for so many 50-, 100-, and 200-kw. transformers as may be required during the year ending June 30th, 1915, at £49 5s., £81, and £125 each respectively, is recommended for acceptance. Other tenders were received from the Foster Engineering Co., Ferranti, Ltd., Brush Electrical Engineering Co., Burnand & Co., William Smit & Co., Brown Boveri & Co., at varying prices. The accepted tender is the lowest for

100- and 200-kw. transformers, and the second lowest for 50-kw. transformers. It was also the second lowest in the period for delivery, viz., eight weeks, compared with six weeks offered by Ferranti, Ltd.

**L.C.C.**—The Highways Committee recommend the acceptance of the tender of the Brush Electrical Engineering Co. for the provision of 150 trailer cars, and the equipment of 200 cars with couplers and traction gear for drawing trailers, at £74,200.

**Manchester.**—The following tenders have been accepted by the Corporation: Five to 6,000-kw. turbo-alternator for Stuart Street Station, British Westinghouse Co.; cable supplies, Western Electric Co. and Chas. Macintosh & Co.; welding rail joints, Tudor Accumulator Co.

**Wrexham.**—The following tenders have been accepted by the Electricity Committee: Dynamo, Lancashire Dynamo Co., at £616 10s.; engine, Belliss & Morcom, at £1,055; condenser, British Westinghouse Co., at £389.

Among recent orders for "Pulsynetic" electric clocks now being carried out by Gent & Co. (Faraday Works, Leicester) are the following installations:—Two C.P.R. boats now building; a new liner for Patrick Henderson & Co.; the Allan Line offices at Montreal; Delhi Station, East Indian Railway; Dominion Bank, Toronto (fifty dials, mostly in marble cases); Henry Birks & Son, Vancouver, B.C.; large striking and chiming turret clock for new Grey Institute, Port Elizabeth, S.A.; turret clock and fifty dials for Australia; astronomical clock for Odessa Observatory; St. Mary's Church, Northampton (four-dial turret clock); Messrs. Ardol, Ltd., Selby; De Montfort Public Hall, Leicester (four-dial hanging clock); Children's Hospital, Leicester; Watson Laidlaw, Glasgow (twenty dials and time bells); Glasgow Corporation (Tramways); Aberdeen Station, N.B. & Caledonian Railways; St. George's School (Glasgow, turret clock with chiming gear); *Edinburgh Evening News* (seventeen dials); Academical Club, Glasgow; Newton Abbot Secondary Schools; Oxford County Asylum.

## APPOINTMENTS AND PERSONAL NOTES

The Rumford medal of the American Academy of Arts and Sciences has been awarded to Dr. W. D. Coolidge, Assistant Director of the research laboratory to the General Electric Co. (Schenectady), for his work on the tungsten lamp and his Röntgen ray tube with tungsten electrodes.

The Manchester Electricity Committee has appointed Mr. H. W. Saunders as Draughtsman, at a salary of £225 per annum.

The Wigan Corporation has decided that Mr. J. Slevin, at present Borough Electrical Engineer and Tramways Manager, shall devote his whole time to the electricity undertaking, and that his salary in future will be £400 per annum, with house, coal, and light.

Mr. H. V. Schofield, of the Newcastle & District Electric Lighting Co., has been appointed Battery Inspector with the Chloride Electrical Storage Co.

We are glad to report that Mr. Edgar Barralet, of Pinchin, Johnson & Co., is now quite out of danger, and is progressing rapidly towards recovery.

The following increases in salary in the Brighton Electricity Department have been sanctioned: Mr. G. Cloughton, Assistant Engineer, from £350 to £375, rising to £400 at the end of twelve months; and Mr. T. Henwood, Mains Engineer, from £205 to £220, rising to £250 at the end of twelve months. A proposal to increase the salary of Mr. G. T. Joyce, Assistant Manager, from £300 to £325 was defeated. It fell to Alderman Gervis to recommend and support these proposals, and in this connection reference may be made to his comments at the I.M.E.A. meeting this year as to the difficulty of inducing the Brighton Town Council to recognise brains adequately.

Mr. L. C. Budd, of the Engineering Staff of the Botulander Automatic Telephone Co., was drowned whilst bathing at Kingston last Saturday.

The late Mr. James Howden, Chairman of Messrs. James Howden & Co., of Glasgow, left personal estate valued at £388,252.

**"Freezor" Fans.**—We hear from the General Electric Co., Ltd. (67 Queen Victoria Street), that owing to large reserve stock that they carry of electric fans of their own manufacture, they are still able to give certain and rapid delivery, in spite of the fact that over 1,200 fans were supplied by them between June 29th and July 4th.

## LOCAL NOTES

**London: Hackney: Bulk Supply.**—A proposal has been made by the Metropolitan Boroughs' Standing Joint Committee that a special meeting, consisting of representatives of the Metropolitan Borough Councils owning electricity undertakings, should consider and report upon the desirability of those Councils taking immediate steps for the joint provision of a bulk supply of electricity. The Hackney Council has been invited to appoint three representatives, but the Electricity Committee reports that it does not think any good purpose will be served by the appointment of the proposed meeting, and recommends that no action be taken in the matter.

**Hampstead: Electric Lighting Profits.**—The net surplus on the electricity undertaking for last year was £6,257, of which £2,162, equal to a rate of 1d. in the £, has been transferred to relief of rates. After making additions to reserve, the balance of £3,871 is carried forward.

**L.C.C.: Bulk Supply Agreement.**—The Council has intimated to the Board of Trade that it has no observations to make with regard to an agreement for bulk supply between the Woolwich Borough Council, the South Metropolitan Electric Light & Power Co., and the West Kent Electric Co. With regard to the agreements between the Stepney and Bethnal Green Councils for a bulk supply, at the suggestion of the Council the Board of Trade has agreed to an alteration to the effect that any dispute as to the accuracy of the meter registering the bulk supply should be referred to the Council.

**Poplar: Electricity Accounts and Loan Periods.**—The net profit for the past year's working was £8,010, as against £3,170 in the previous twelve months. To this has been added the unappropriated balance from the previous year of £2,691. The Committee recommends that £2,433 be appropriated for displaced machinery and various other items, including services and meters, £2,402, wiring installations, £967, and cooking installations, £91, leaving an unappropriated balance of £4,817 to be carried forward. Owing to the agreement between the Poplar and Stepney Councils for mutual bulk supply, it is not anticipated that further plant extensions will be required until 1917. Mr. Horace Bowden, the Borough Electrical Engineer, referring to the recent revision by the L.C.C. of the maximum periods for repayment of loans, viz., land, sixty years, buildings, thirty years, mains, twenty-five years, machinery, fifteen years, services, twelve years, and meters, ten years, said that he has hitherto advocated a policy of borrowing only for periods of twenty years and over. The action of the L.C.C. is, he considers, most drastic, and places severe restrictions upon expansion of business. The working costs are 0.55d. per unit, and constitute a record for the Metropolitan area.

**Newcastle-under-Lyne: Supply to Small Houses.**—Mr. A. J. C. de Renzi, the Borough Electrical Engineer, is preparing a scheme for the wiring of small houses at a cost of from £5 to £10 each according to size, the idea being to work in conjunction with contractors, and for the consumers to enter into hire-purchase agreements.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday, night was £63 10s. to £64. (Last week, £62 5s. to £62 16s.)

**Works Holidays.**—T. W. Broadbent, Ltd. (Victoria Electrical Works, Huddersfield), inform us that their works will be closed from Friday night, July 24th, to Tuesday morning, August 4th.

The works of the Record Electrical Co., Ltd., will be closed from Friday evening, July 31st, till Monday morning, August 10th.

**Reduction in Prices of Wires and Cables.**—The India-rubber, Gutta-percha & Telegraph Works Co., Ltd. (106 Cannon Street, E.C.), announce reductions in the prices of some of their rubber-insulated wires and cables. Their discounts on 2,500, 600, and 300 megohm 600-volt C.M.A. and Association pure india-rubber flexibles are now 33½, 15, and 10 per cent. respectively. Reductions are also announced by Siemens Bros. & Co., Ltd. (Woolwich).

**The New Ediswan Showrooms.**—The trade entrance of the new showrooms of the Edison & Swan United Electric Light Co., Ltd., at 123-125 Queen Victoria Street, is at 228-229 Upper Thames Street, E.C.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**General Electric Co.**—Mr. H. Hirst, presiding at the annual meeting on Friday, called attention to the very satisfactory result of the past year's trading, viz., a net profit of £157,893, against £145,260 in the previous twelve months. After adding the balance brought forward there was a total of £190,224 to be distributed. Of this £8,000 is absorbed by debenture interest, and £24,328 in depreciation. The directors have put aside the same generous amount as in past years, but the state of the books permits the use of £10,000 for removal expenses in connection with the Kingsway building. In addition a sum of £10,156 has been provided for managing directors' and employees' bonus, and £14,000 towards writing off the expenses of the new issue of capital, and a carry forward of £36,739 remains after paying 10 per cent. on the ordinary shares. Special attention was called to the fact that the reserve fund now equals the whole of the debenture issue. Mr. Hirst emphasised the point that whereas the Company was to a large extent identified with the small electric supplies business, it was a fact that the progressive results of the past year's trading had been principally due to the expansion of the engineering and other departments. It was true, he said, that the growing demand for domestic electrical apparatus claimed a considerable part of the Company's capital and attention, but it was too little realised that the G.E.C. is in the front rank of those supplying the world with large electrical machinery. Already the Company had produced machines up to 6,000 kw., and hoped to go still further. The latest important development was the establishment of a cable works at Southampton in conjunction with Messrs. Pirelli, both companies subscribing 50 per cent. each of the £200,000 capital. These works are now completed, and it was hoped within a few months to supply cable and wire from these works at a price that would compare favourably with that of any other firm. No questions were asked by the shareholders, and the report and accounts were adopted.

**Edmundsons' Electricity Corporation.**—The report for last year shows that the Company continues to make steady progress. The gross trading profit increased by £912, and dividends and interest increased by £1,640. The loss on working local authorities' undertakings is reduced by £136. The net profit, after providing for debenture interest and redemption, is £23,125, an increase of £4,225. After carrying £9,000 to reserve, the final dividend on the cumulative preference shares absorbs £6,000, and the balance is carried forward.

**Crompton & Co.**—The first accounts of the reconstructed company show an available balance of £13,550, after meeting depreciation and debenture interest. The sum of £2,500 is to be placed to reserve, £1,500 is to be written off preliminary expenses, the 5 per cent. preference dividend absorbs £4,391, and the balance of £2,189 is carried forward. The directors report that the reconstruction of the company has had a beneficial effect on the business, all departments of the company are fully employed, and the outlook for the current year is promising.

**Consolidated Diesel Engine Manufacturers.**—An order for the compulsory winding up of this company was made in the Chancery Division by Mr. Justice Astbury on Tuesday.

**Compulsory Tungsten Filament Lamp License.**—Before Mr. Justice Warrington, on Monday, the Robin Electric Lamp Co., Ltd., applied for particulars of the grounds of opposition of the British Thomson-Houston Co. and Siemens Bros. & Co. to a petition for a grant of a compulsory license to manufacture metal filament lamps under the tungsten lamp patents. Mr. Cave, K.C., said that so far all the companies manufacturing these lamps, with the exception of the B.T.H. Co., had declined to give the Robin Co. a supply of tungsten. The B.T.H. Co. had offered to supply wire at 125s. per thousand feet, which was unreasonable, as it could be bought abroad at 40s. per thousand feet. The companies opposing the application for a compulsory license said that the requirements of the public were already satisfied, and that sufficient licenses had already been granted. Mr. A. J. Walter, K.C., and Mr. H. A. Colefax, K.C., on behalf of the B.T.H. Co. and Siemens Bros. & Co., respectively opposed the application for particulars of the grounds of opposition, and urged that the patentees ought not to be compelled to disclose private trade transactions and bargains with their licensees.

**I.M.E.A. Bill.**—This Bill was introduced into the House of Commons by Sir William Howell Davies last week, and read a first time. We gave a summary of its contents in our issue for March 5th, p. 127.

## SUMMARY

THE electrical section of the British Standards Committee has been reorganised, and its committee is now the same as the British Committee of the International Electrotechnical Commission. A large number of sub-committees have been formed. Among the subjects now being worked on are electrical machinery, meters, ceiling roses, plugs and sockets, cables and lamps. (Page 406.)

SEVERAL matters of importance in relation to electricity supply in London are reported. The City of London Corporation does not propose to give notice to purchase the City of London and Charing Cross Companies undertakings; a Special Committee of Metropolitan Borough Councils is to investigate the question of bulk supply, and the L.C.C. has refused to convene a conference with the Borough Councils on the question of periods of repayment of loans. (Page 406.)

THE Annual Report of the Chief Inspector of Factories includes the Report of Mr. G. S. Ram, the Electrical Inspector, who reports a slight increase in accidents from electrical causes but a decrease in the fatalities as compared with last year. An increase is reported in lead-poisoning in accumulator factories. (Page 407.)

A RESEARCH is in progress at the National Physical Laboratory on the heating of buried cables. This is being done at the request of the Research Committee of the Institution of Electrical Engineers. (Page 407.)

QUESTIONS relating to electrolytic lighting arrester and to the running of a three-phase motor are propounded in our Questions and Answers columns. (Page 408.)

THE work of the International Commission for Wire-

less Telegraph Research is now in full swing.—Sir Ernest Shackleton has appealed for funds for a wireless telegraph equipment for his Antarctic expedition.—The hearing of the Marconi v. Helsby wireless patent case was concluded on Tuesday last. Judgment was reserved.—The use of automatic telephone exchanges is to be extended by the Post Office. (Page 408.)

THE question of whether motor-omnibuses shall contribute directly to road maintenance is to be dealt with by a Departmental Committee. (Page 409.)

THE specification relating to the Ferranti-Waters' reverse power relay was amongst those published last week.—Patents for the treatment of magnetic steel and for the manufacture of ductile tungsten have been granted to the B.T.H. Co. and C. Trenzen respectively, notwithstanding the opposition raised.—A patent for a simple construction of field-magnet windings expires this week after a full life. (Page 410.)

OUR Trade Section contains a description of a new switch and illustrates installations of half-watt lamps. (Page 411.)

EXTENSIONS are contemplated at Manchester (£68,000); Burton-on-Trent (£7,000); Redditch (£18,000); Dublin (£82,000); East London (S.A.) (£775); and Oldham (£40,000).—A cooling tower is required at Aldershot; battery, booster and switchgear at Grimsby; flame arc lamps, etc., at Salford; meters and motors at Ashton-under-Lyne; cable at Turton; and sub-station switchgear at Manchester. (Page 413.)

A PROPOSAL to meet the cost of two cooling towers out of the reserve fund at Sheffield has met with considerable opposition.—A L.G.B. inspector severely criticised last week the action of the Manchester Corporation in paying large sums out of electricity profits for relief of rates, and immediately coming for borrowing powers for such things as motors.—The turbo-generator which broke down at the L.C.C. power station early in the year has cost £1,615 to repair.—A proposal for bulk supply has been submitted to the Dover Corporation by the South-East Kent Electric Power Co. (Page 414.)

**Switchgear Tenders.**—We have received a copy of a letter which has been addressed to the Secretary of the I.M.E.A. by the B.E.A.M.A., calling attention to the difficulty and expense which contractors are asked to incur in tendering for switchgear, with particular reference to a recent case at Dundalk, where the prices had to be split up into separate items. It will be remembered that the subject was dealt with in a letter published in ELECTRICAL ENGINEERING, October 31st, 1912, when attention was drawn to the enormous number of unnecessary drawings which switchboard contractors and sub-contractors were often called upon to make. The Secretary of the I.M.E.A. has replied that, although an opportunity will not arise for some time for the Council to consider the matter, he feels sure that they sympathise with the expressions contained in the letter, and points out that they have, in fact, already expressed their views in this connection.

## THE ENGINEERING STANDARDS COMMITTEE

IN consultation with the Institution of Electrical Engineers, the Electrical Section of the Engineering Standards Committee has lately been reorganised. The Institution is now represented on the Main Committee by Col. R. E. Crompton, Sir John Snell, and Mr. C. P. Sparks, and the new Sectional Electrical Committee is the British Committee of the International Electrotechnical Commission. This Committee is now constituted as follows. (The bodies represented by individual members are given in brackets.) :—

Sir John Snell, *Chairman* (Crown Agents for the Colonies); Messrs. A. Siemens and C. P. Sparks, *Vice-Chairmen*; Mr. C. H. Wordingham (Admiralty); Capt. G. L. Hall (War Office); Mr. M. G. Simpson (India Office); Mr. G. S. Ram (Home Office); Mr. W. Slingo (Post Office); Mr. H. A. McFerran (Office of Works); Dr. R. T. Glazebrook (National Physical Laboratory); Messrs. W. Duddell, F. Gill, R. Hammond, J. S. Highfield, and R. T. Smith (I.E.E.); Messrs. A. C. Cramb and A. H. Seabrook (I.M.E.A.); Messrs. C. Koettgen, P. A. Lange, and A. P. Wood (B.E.A.M.A.); Mr. W. R. Rawlings (Electrical Contractors' Association); Mr. E. T. Ruthven-Murray (Incorporated Association of Electrical Power Companies); Mr. S. Sellon (Tramways & Lt. Rlys. Assoc.); Col. R. E. Crompton, Sir John Gavey, Mr. W. Judd, Dr. Gisbert Kapp, Prof. T. Mather, Mr. C. H. Merz, Mr. H. W. Miller, Dr. A. Russell, Capt. H. R. Sankey, Dr. S. P. Thompson, Mr. A. P. Trotter, and Mr. P. F. Rowell, *Hon. Sec.* A representative of the L.C.C. has yet to be nominated. Mr. A. Siemens takes the chair when questions affecting the I.E.C. are discussed.

The following are the chairmen of sub-committees :—Dr. Glazebrook (Standardisation of Electrical Machinery, Physical Standards, and Lamps); C. P. Sparks (Power Cables); Mr. C. H. Wordingham (Electrical Accessories); Sir John Gavey (Telegraphs and Telephones); Capt. H. R. Sankey (Prime Movers); Mr. A. P. Trotter (Nomenclature); Dr. A. Russell (Symbols). There will also be "Panels" on Rating of Electrical Machinery presided over by Dr. Glazebrook, and on meters, plugs, switches, fuses, heating and cooking apparatus, carbon brushes, control gear, and electric vehicle accessories, presided over by Mr. C. H. Wordingham.

The British Committee has nominated the following delegates to the Special International Committees of the I.E.C. :—Nomenclature, Dr. S. P. Thompson; Prime Movers, Mr. Gerald Stoney; Rating, Dr. Gisbert Kapp; and Symbols, Dr. A. Russell. Mr. A. R. Everest (B.E.A.M.A.) has again been appointed as counsel to the British delegate on Rating.

The work at present in hand consists both of revision and new work. A preliminary draft of the British Standardisation Rules for Electrical Machinery is being drawn up in co-operation with the Revision Committee of the American Standardisation Rules. The specification for electric meters is also under revision, and a specification for two- and three-plate ceiling roses will be published almost immediately, as well as a report on the specifying of the resistance of steel conductor rails. Progress is also being made in regard to the standardisation of two-pin plug and socket devices, a specification for which should be ready in the autumn. Through the assistance of the B.E.A.M.A. it is also hoped that considerable progress may be made in regard to the standardisation of a number of other accessories. In this connection, the Committee is co-operating with the Electric Vehicle Committee of the I.M.E.A. The report on cables is to be revised and extended, and the work upon a revised specification of carbon and metal-filament lamps is to be continued. The question of tungsten filament electric lamps for automobiles is also being considered at the request of the Society of Motor Manufacturers and Traders, by a Sub-Committee under the Chairmanship of Col. H. C. L. Holden.

### Gas Co.'s Action against the Ilford Electricity Department.

—In connection with our comment on this subject in our last issue, Mr. H. Faraday Proctor, Hon. Sec. of the Incorporated Municipal Electrical Association, writes us that he had already taken up this matter some time ago, and has had considerable correspondence both with the Clerk to the Long Eaton U.D.C. and also, more recently, with Ilford. We are glad to see that the I.M.E.A. is proposing to act officially in the matter, and we trust that it will be somewhat on the lines indicated in our last issue, viz., that a clear definition of what is and what is not preferential charging should be arrived at, and that the I.M.E.A. should be prepared to support this definition to its utmost ability. On the other hand, the question of hiring powers for motors cannot be settled, except by the obvious method that those Corporations who do not possess hiring powers and who wish to hire out motors should obtain them.

## FUTURE OF LONDON'S ELECTRICITY SUPPLY

THE Borough Councils in London are apparently not satisfied to leave matters at a standstill whilst the London County Council is deciding what steps to take in connection with Messrs. Merz and McLellan's report on the future of London's electricity supply. We reported in our last issue that the Metropolitan Boroughs' Standing Joint Committee proposed to appoint a Special Committee to consider and report upon the desirability of the Metropolitan Boroughs owning electricity works taking immediate steps for the joint provision of a bulk supply of electricity. Although, as we stated last week, the Hackney Council did not agree with the proposition, nevertheless this Special Committee has been formed, and presumably will get to work immediately.

As there has been considerable reluctance on the part of the L.C.C. in some cases to grant sanction for loans for extensions of Metropolitan Borough electrical undertakings which are obviously required to meet the statutory obligations on account of increasing demands, the L.C.C. has been asked to call a conference of such Councils with a view to discussing the whole of the question of repayment of loans. The matter was referred to in a "Local Note" last week dealing with the Poplar accounts, but the request has been refused on the ground that the matter would be more appropriately dealt with by a deputation to the Council. The Clerk to the Poplar Council has now written expressing the deep regret and keen disappointment of that body that the L.C.C. has once more refused to recommend the convening of a conference, and at the same time strongly deprecates the L.C.C.'s action in view of the importance of the matter.

When the recommendation of the Committee was brought before the Council on Tuesday, Mr. H. H. Gordon moved its rejection, and urged the necessity for calling a conference. This was supported by another progressive member of the Council, but the Chairman of the Finance Committee said that only two or three weeks ago the Council, by a non-party vote, decided to offer to convene a conference to deal generally with the question of electric supply, but excluding the question of the periods for the repayment of loans, as in this matter the County Council exercised a statutory discretion. This offer, however, has been declined by the Borough Councils. The rejection of the report was negatived by 51 votes to 30.

The position of electricity supply in the City has also been receiving attention during the last few days, so far as the possible purchase of the City of London and Charing Cross Cos.' undertakings in the city are concerned. In 1912 the City Corporation obtained the opinion of the late Mr. W. C. Danckwerts, K.C., who expressed the view that the City Corporation could purchase the undertakings of the Companies by giving them six months' notice on August 18th, 1914, or August 18th, 1924. The City of London Co., on the other hand, have taken the advice of Sir Robert Finlay, K.C., Mr. George Cave, K.C., and Mr. Tyldesley Jones, whose opinions differ from those of the late Mr. Danckwerts. Their view is that the Corporation will have no right to purchase the undertaking of the City Co. if it does not give notice as from August 18th. The Streets Committee of the Corporation, however, recommended at the meeting on Thursday that it would be inexpedient to exercise the powers to purchase in 1914-15. There was no discussion upon this report.

**University College, London.**—In the Faculty of Engineering, the following awards have been made :—Chadwick Medal and Prize, J. A. Parker; Andrews Scholarship (2nd year), J. Mould; Goldsmid Scholarship (2nd year), H. P. Gardham; (3rd year), P. L. Capper; Archibald P. Head Medal and Prize, Z. S. Quai. Engineering Diplomas :—A. Arias (Electrical), G. G. Dawson (Electrical), W. J. Duncan (Mechanical), C. C. R. Edwards (Mechanical), G. H. Elliot (Civil), G. V. P. Filsell (Civil and Municipal), A. E. Griffin (Civil and Municipal), Z. S. Quai (Civil and Municipal), P. W. Miller (Civil and Municipal), A. Mylting (Civil and Municipal), J. A. Parker (Civil and Municipal), J. R. Pigott (Mechanical), F. Procter (Civil and Municipal), D. M. Rowland (Civil and Municipal), P. Schur (Civil and Municipal), D. G. Trouton (Electrical), and W. J. Wells (Civil and Municipal).

**The West Ham Electricity Works.**—A special summer issue of the West Ham Corporation Electric Service half-yearly bulletin contains an illustrated description of the generating station at Canning Town, including the large extensions recently completed. These extensions were described in *ELECTRICAL ENGINEERING*, Vol. IX., June 12th, 1913, page 339, and contain several points of special interest, including the suction plant for ash disposal, the turbo-generators, and the very compact coal-handling plant. Notes on the sales department and on the special arrangements for charging electric vehicles.

## ELECTRICITY IN FACTORIES AND WORKSHOPS

THE Annual Report of the Chief Inspector of Factories and Workshops for 1913 contains in its various sections several references to electrical matters, including the report of Mr. G. Scott Ram, the Electrical Inspector. The Divisional Report states that the increased use of electricity as a motive power is not less remarkable than in previous years, and is noticeable in all parts of the country; it is specially commented upon in Scotland, where the strenuous efforts made by the Town Councils to get traders to adopt this form of power have resulted in many small joiners, tailors, watchmakers, bootmakers, and others putting in electric motors, even in places where only two or three hands are employed.

Mr. Ram's Report records 392 non-electrical (including seven fatalities) and sixty-five electrical accidents (two of them fatal) at public supply stations, and forty-seven non-electrical and twenty-nine electrical accidents (only one of the latter fatal) at other stations. The non-electrical accidents show an increase of 18 per cent. over the previous year, and were such as are liable to occur in engineering works generally. The electrical accidents, writes Mr. Ram, are remarkably few in view of the large number of stations. The total is greater than last year, but the fatalities less. Forty-six per cent. of them were due to working on live switchboards, and a large proportion were of a clearly preventable nature. In this class are two fatalities on medium-pressure circuits. The only other electrical fatality was to a man working inside a boiler who was provided with a faulty hand-lamp.

The electrical accidents reported at factories other than generating stations were 418 in number (against 283 for the previous year), of which seventeen were fatal (against fifteen for the previous year). They are classified as follows: Arcing of switches, 56; arcing of fuses, 17; shock or burns when replacing fuse wires, 35 (one fatal); portable apparatus, 66 (three fatal); unprotected conductors, 42 (five fatal); working on or near live conductors, skilled persons 42 (three fatal), unskilled persons, 43 (two fatal); miscellaneous in manufacturing and repair works, mostly in testing, 66 (one fatal); brushes and commutators, 10; miscellaneous, 41 (two fatal). The increase over the previous year is hardly surprising, in view of the enormous extension in the use of electrical energy. A large number of the accidents are reported as having been due to inadequate skilled supervision, both as regards initial selection and installation of the plant and its subsequent working and maintenance; this is particularly so in those due to arcing of switches and fuses. The three fatalities in connection with portable apparatus were all due to the use of hand-lamps of obsolete type, with the lamp-holder in connection with the other metal-work which was not earthed. There were several narrow escapes in hand-lamp accidents; in one case the connections of an auto-transformer were such that although there was only 110 volts across the lamp, the pressure to earth was the full 440 volts. The majority of the accidents in the use of portable apparatus occur in the handling of the connectors and flexible conductors. One of the fatalities in the next class was due to non-earthing of the guide wires and winch of the lowering gear of an arc lamp; several of these accidents also occurred on electric cranes. Most of the accidents to "skilled" persons working on live conductors need not have occurred, "the persons concerned being acquainted with the dangers, having often only themselves to blame for not taking proper precautions. The corresponding accidents to unskilled persons," continues the Report, "differ in this respect. The victims, having little or no knowledge of the dangers, are put to work, or are permitted to work, under dangerous conditions without proper precautions or supervision by competent persons in authority over them. In most cases there could have been no necessity for the work to be undertaken whilst the conductors were 'live.' The number of accidents in electrical manufacturing works has more than doubled. This is no doubt generally an indication of increased activity in manufacturing, leading to pressure of work in the testing departments of the works concerned. The fatal accident occurred in the testing department of a cable works, and was primarily due to a mistake in switching. Amongst the miscellaneous accidents, one was due to an old form of practical joke—a live wire being attached to a door-handle. A similar joke a year or two ago had fatal consequences. In the present case the victim received a serious shock, but recovered. In the two fatal cases death was due to fall."

Mr. Ram reports that in his visits to works during the year he found numerous examples of dangerous conditions both in old and new installations, and in many cases regards it as

purely a matter of good fortune that accidents had not occurred. In a number of cases he found passage-ways in which bare conductors were exposed all along the side without any protection. Some high-tension gear was constructed without any provision for screening off adjacent live conductors while work was in progress. Oil-switches, for example, were placed close to bare bus-bars in such a way that although they would be disconnected by isolating switches, the live conductors could not be screened. In one station the oil-switches could not be made dead without interrupting the supply. Several cases were found where new switchboards were erected, having less than the required space at the back, a mistake for which there is obviously no excuse. A number of 440-volt three-phase switchboards were found having iron plating for the working platform, and no "insulating stands." A large number of distribution fuse-boards for power circuits were found having fuses which could not be handled without risk of touching live metal, and many for lighting circuits having the additional defect that the hand is liable to be burned by the blowing of the fuse. One extensive power and lighting installation, 440-volts three-phase, put up by a foreign firm of contractors, was dangerous in almost every conceivable way. There was bare switchgear over iron floors, and some out-of-doors, bare conductors within reach. There was no means of cutting off the pressure from the power circuits except by shutting everything down at the main switch in the sub-station some distance away, and for the lighting circuits the main switch did not cut off the pressure. The lighting was taken from a fourth neutral wire, and one or other of the phase wires. The main switch did not break on the neutral conductor, and this was not earthed, so that it was liable to be live at 250 volts above earth, even with the main switch off. It would appear that competition and consequent cutting of prices was often responsible for work not being in accordance with the requirements.

In the Divisional Report, the question of the temperature and ventilation of incandescent lamp factories is referred to, and a case where the temperature is successfully kept down by a continual supply of cool, fresh air in a lampworks in the Midlands is referred to. In the South-Eastern District the matter of ventilation of lampworks has been specially under observation, and the results were most satisfactory.

In dealing with dangerous trades, the increasing manufacture of accumulators, particularly in connection with the motor-car trade, is mentioned, and the success of localised ventilation to the benches to combat lead-poisoning is referred to. The medical inspectors, however, report an increase in poisoning cases from this cause, and urge the necessity of further adoption of these precautions. Two cases of mercurial poisoning are also reported in the manufacture of electricity meters and mercury vapour lamps respectively.

## THE HEATING OF BURIED CABLES

THE Research Committee of the Institution of Electrical Engineers recently appointed a sub-committee to consider the question of the heating of buried cables, and subsequently decided to make a grant in aid of a research on the subject. A summary of the present knowledge in this direction has been prepared by Messrs. S. W. Melsom and H. C. Booth, of the National Physical Laboratory, and is published together with some other notes on the progress of the research in the Journal of the Institution. This goes into the matter theoretically, reviewing the formulae of Kenelly, Teichmüller, Abt, and others, and summarises experimental work and deductions of a number of workers and their bearing on the rules drawn up by a Commission of the Verband Deutscher Electrotechniker. From this it appears that while the constants for armoured cables laid direct in the ground are fairly well known, there is little information cables drawn into conduits or laid solid in bitumen. The German tables for armoured cables, however, probably represent rather different conditions from those obtaining here. There is also some doubt as to the certain assumptions made in the formulae. The matter is much complicated by the varying conditions of the soil and method of laying, and preliminary experiments show results differing by as much as 100 per cent. Although there has been much preparation; the main experimental work was not yet commenced at the time of the report. The research will be divided into two parts. The first will consist of a series of tests on lengths of cable laid on various systems in the grounds of the National Physical Laboratory, and the second part of tests on actual mains under as nearly as possible actual conditions. The principal points to which the research will be directed are to obtain definite information as to the temperature of and the moisture in the soil, the determination

of the thermal constants of the soil, of the cable coverings, and of the various ducts. The heating of cables when laid (a) direct in the ground, (b) solid in bitumen, and (c) drawn into ducts, the external thermal conditions being the same. The temperature attained by mains in actual service and the load-factor of the cables. The determination of the watts lost in different types of cable with alternating current.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,400.

In connection with aluminium electrolytic lightning arresters, what is the electrolyte (giving a critical A.C. voltage of about 300) that is generally used? Is it true that only one wave of the alternating current produces the insulating film by converting the aluminium in hydroxide, while the opposite wave has no effect. Also, is it necessary to form the film or even part of it before assembling the aluminium trays?—"ARRESTER."

(Replies must be received not later than first post, July 23rd.)

### QUESTION No. 1,398.

A three-phase slip-ring motor generator, 400 h.p. 2,200 volts, is loaded about 35 per cent., and is supplied from a distant power station  $2\frac{1}{2}$  miles away, through aluminium lines 37/12 S.W.G. The motor runs satisfactorily until another motor of 300 h.p. is switched in circuit, when a heavy thump is heard shaking the foundation and breaking the bridge connections of rotor winding each time the second motor is switched in; this machine is controlled with reversing switch, and is 500 yds. further away. The thump is not heard in the motor when switching on the motor-generator. The starting current of the motor is about 50 amps. at 2,200 volts.

Can I do anything to prevent this heavy thump?—"DEAD EARTH."

As no replies have been received, the time for answering this question has been extended till July 23rd.

## "Prana" Die Castings

will lighten your costs very considerably.

They leave the dies in a finished, ready-

for-use state, accurate to a degree only obtainable (by other methods) by long and costly "micro-machining." In addition to this each one is an exact duplicate of all the others—and so all die cast parts are automatically interchangeable, but they must be "Prana."

**AERATORS Ltd., UPPER EDMONTON, N.**

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The International Commission for Radio-Telegraphic Research, which was inaugurated at a meeting in Brussels in April last, has held a further meeting, at which its constitution has been adopted in definite form. Mr. W. Duddell is President, Prof. Wien, Vice-President, Dr. R. Goldschmidt, General Secretary, and Mr. R. Brailard, Assistant Secretary. National Committees have been formed in Belgium, France, and Great Britain. A large number of technical matters were brought up at the meeting. Dr. Goldschmidt described the latest improvements at the Laeken station, and it was decided that a small high-frequency alternator be acquired. Reports were also read by Prof. Schmidt (Halle) on observations by a barometer and galvanometer by Messrs. Vollmer and Wien (Jena), Dr. Marchant (Liverpool), Mr. Lucas (Namur), and Mr. Wulf (Volkenburg), on photographic registration of signals, by Mr. Bonndorf (Graz) on reception of signals from Brussels at a distance of 2,000 km. by a detector and galvanometer, and by Prof. Howe (London) on the determination of the energy received from Brussels and Paris. In the discussion on these the Commission expressed the wish that experimenters would send in with their results characteristics of their antennae, and that wherever possible should employ photographic registration. Mr. Duddell also read a Paper on methods to be employed, and suggested the employment of a closed receiving circuit at the control station similar to that used by Mr. Braun (Strassburg). Communications were also read by Mr. Abraham (Paris) on measurements of the velocity of propagation of waves between Paris and Washington by his narrow coil galvanometer; by Mr. Vollmer on the non-constancy of crystal detectors; by Prof. Wien on the thermal inertia of thermo-elements, and by Mr. Drumeaux (Brussels) on amplification and production of waves oscillation by "von Lieben" valves. Arising out of this communication Prof. Wien described a method of quickly determining resonance curves of the von Lieben tube in order to obtain antenna constants. Dr. Eccles read a report on the steps taken by the B.A. Committee regarding the solar eclipse of August 21st, and a special committee, consisting of Messrs. Bonndorf, Eccles, Ferrié, and Wien, was nominated to consider the matter.

The success of Dr. Mawson's wireless telegraph equipment, by means of which his base on the Antarctic Continent was kept in touch with the rest of the world through his other station at Macquarie Island, directed a good deal of attention to the possibilities of wireless communication for Polar exploration work, and it is to be hoped that the desired funds will be forthcoming so that Sir Ernest Shackleton's Antarctic expedition can be provided with all they want in this direction. There is also much experimental work of interest that could be done if his party were able to establish fairly powerful stations at the two proposed bases—one on each side of the Continent. First of all, there is some question as to whether communication could be maintained at all between them, owing to the height of the mountain ranges intervening and the probable high degree of ionisation of the air in polar regions, apart from the difficulties of maintaining high aerials in the violent winds that are experienced. There are many problems regarding the effect on wireless transmission of the extreme climatic and meteorological conditions that might be studied. It is to be hoped, too, that it will be found possible to devise a satisfactory sledging set within a practicable weight limit, but a good deal of experimenting will probably be required as to a suitable form of aerial and earth connection or its equivalent. Possibly when on the high ground near the Pole, aerials of quite small size will be found sufficient. It will be remembered that Amundsen is equipping the *Fram* with a wireless installation for his North Pole expedition, and is also providing some form of portable sledge outfit. Telephones have already been used with success for base work. Capt. Scott's main base was connected by a line fifteen miles to Hut Point, and other short lines were in constant use for meteorological and astronomical work. In these cases bare aluminium wires resting on the snow were used for the lines. If such an arrangement could take the place of raised aerials for the wireless work, the problem would be much simplified.

The Bradford Corporation has decided to call a conference of Corporations in the West Riding of Yorkshire to consider a scheme under which the control of the telephone service in this area shall be under municipal control.

In an article in the *Nineteenth Century and After*, entitled "An Inter-Imperial Cable Link," Mr. Charles Bright, F.R.S.E., deplores the passing of the control of the Atlantic cables into American hands, and the transfer of the Government landing licences, and puts in a strong plea for a British State-controlled Atlantic cable to act as a connecting-link with the Pacific cable. He discusses a proposed route for such a cable, and dwells on the strategic and political aspects of the question, and easily disposes of financial difficulties. The same subject was dealt with by Mr. Bright from a slightly different point of view in a Paper read recently before the Royal Society of Arts on "The Administration of Imperial Telegraphs," in which he advocated centralised Government control of inter-Imperial communication, and pressed for a Royal Commission to study the subject. A certain amount of divergence of opinion was voiced in the discussion, and in a written communication Major W. A. J. O'Meara (late Engineer-in-Chief to the Post Office) expressed his conviction that State management of so highly technical a service as submarine telegraphy would defeat the very object that Mr. Bright had in view.

The report of Marconi's Wireless Telegraph Co. for the past year, although recommending final dividends making 17 per cent. on the preference shares and 20 per cent. on the ordinary shares for the year, shows a considerable decrease in the net profits, viz., from £413,294 to £122,323. This is largely accounted for by unremunerative expenditure in connection with the Imperial wireless telegraph scheme, whilst the Directors also reminded the shareholders that the substantial profits made for 1912 were realised under exceptional circumstances. The Trans-Oceanic Wireless Telegraph Co., which was registered last year, has taken over the new stations in Wales for the purpose of conducting a wireless telegraph service between this country and the United States. It is anticipated that when this service gets into working order a speed of 100 words per minute will be automatically maintained. The report adds that rapid progress has been made in the development of wireless telephone apparatus, and that the Company has recently introduced a practical and commercial set for moderate distances.

In reply to a question in the House of Commons last week, the Postmaster-General stated that the experimental automatic equipment at Epsom has proved fairly satisfactory. Arrangements have been made to apply automatic systems to the districts of Accrington (700 lines), Darlington (800 lines), Dudley (500 lines), Grimsby (1,300 lines), Newport (1,800 lines), Paisley (1,100 lines), Portsmouth (5,000 lines), Stockport (950 lines), and Leeds (6,800 lines). The Darlington exchange (on the Western Electric Co.'s system) will be opened in a few weeks' time, and an experimental equipment for sixty-five subscribers is to be installed at Chepstow to test the suitability of automatic apparatus for very small exchanges.

On Monday, July 13th, the hearing of the Marconi v. Helsby wireless telegraph patent case was continued before Mr. Justice Eve. Mr. Jaffé, in his speech for the defendants, touched upon the several points which had been mentioned in the course of the proceedings, laying particular stress upon the finding of Mr. Justice Parker in the previous case that Marconi's invention was for a persistently oscillating circuit coupled to a good radiator, so that the former acts as a reservoir for the latter. The defendants' apparatus, he submitted, had not a persistently oscillating primary circuit. On the contrary, the aerial circuit, owing to its comparatively large capacity, was the persistent oscillator. The advantages of this as compared to the Marconi arrangement were, he said, improved selectivity between the sending and receiving stations, and less waste of energy. Dealing with the plea of invalidity, counsel pointed out that the documents upon which the defendants relied had not been cited in the previous case before Mr. Justice Parker. He recalled the evidence of Mr. Swinburne to the effect that once Marconi knew what he wanted, he probably could have made use of Tesla's apparatus for his purpose. The discovery of a new use for a known product, he argued, was not patentable.

The speech for the plaintiffs was commenced by Mr. Walter, who, quoting from Marconi's patent No. 7,777/00, gave the claim as for a transmitter for electric wave telegraphy, consisting of a primary circuit coupled inductively to a conductor or capacity and earth. There was no limitation as to the capacity of the aerial. The Helsby apparatus, he contended, was the same as that described in Marconi's specification, except that here were more spark gaps. Dealing with the question of economical working, he referred to the evidence which had been given showing that with the amount of coupling between the primary and secondary circuits which

the defendants used, only a very small percentage of the energy in the primary could pass over into the secondary during the three and a half complete swings which were said to make up the primary spark. Regarding the documents of Tesla and M. Dueret, which were cited as anticipatory, it could not be denied, he said, that these two writers did not teach the world the substance of Marconi's invention. Mr. Hunter Gray, who also spoke for the plaintiffs, in addition to emphasising the points mentioned by Mr. Walter, submitted that even assuming that the defendants' apparatus does give a primary spark with only three and a half swings, whilst Marconi's apparatus yields, say, a fifty-swing spark, the difference was only in degree, and was therefore not essential. His Lordship reserved judgment.

A wireless telephone has been installed at Scranton, Pennsylvania, by which communication with an express train travelling at 60 miles an hour has been established over a distance of 53 miles. The telephone is of the de Forest type, and the antenna of Scranton is 300 ft. long, and has an elevation of 150 ft.; the power required was approximately 1 kilowatt. It is intended to equip two of the fast trains with this apparatus for public use.

According to the *Daily Telegraph*, two engineers of the Marconi Co. have arrived at Bombay in connection with the Indian wireless telegraph station which forms part of the Imperial scheme.

The Ahvaz-Mohammerch landline is again in working order, and the Fao route was restored on the 9th inst.—The cable between Nagasaki and Tamsui was repaired on the same date, and the new route to the Belgian Congo "via Banana" was opened.

## ELECTRIC TRACTION NOTES

The question of whether motor omnibuses shall contribute towards the upkeep of the roads—an important matter in relation to their competition with tramways—has at last reached the point where the Government has promised to take action. A Departmental Committee has been promised to deal with the whole question of whether both motor omnibuses and trolley omnibuses should contribute towards the maintenance of roads. Simultaneously with the announcement of this Committee have been several decisions of Parliamentary committees which will compel motor omnibus companies and also municipalities running omnibuses outside their own areas to contribute towards road maintenance. Chiefly in this connection may be mentioned the new main road which it is proposed to construct to the west of London, where a toll of three-eighths of a penny per bus-mile will have to be paid by the omnibus companies using the road, whilst cases this session in the provinces of municipalities being put under similar conditions where they run omnibuses outside their own areas on the County roads may be cited at Sheffield and Walsall.

The Bradford Corporation Tramways made a net profit last year of £29,500, against £41,900 in the previous twelve months. The sum of £10,000 is carried to relief of rates, and the balance transferred to reserve, which now stands at £73,000.

The poll of ratepayers at Bristol with regard to the purchase of the Tramway Co.'s undertaking resulted in a small majority in favour, and the Ratepayers' Association has passed a resolution to the effect that the result of the poll does not justify the Corporation proceeding with the Bill to purchase the trams. Something like 40,000 ratepayers did not vote.

The local authorities whose districts are served by the Oldham, Ashton, and Hyde Electric Tramways Co. are considering what steps should be taken to acquire the undertaking, the lease of which expires shortly.

There was a net profit of £53,892 from the working of the Glasgow Corporation Tramways last year. The whole of this is to be paid over to the Common Good, as before arriving at this figure £127,204 has been transferred to depreciation fund, and £85,438 to permanent-way renewals fund.

The West Ham Corporation Tramways Department incurred a loss of £14,422 last year, after meeting capital charges. In addition it has been necessary to realise part of the investments to cover the cost of renewals, with the result that the reserve and renewals fund is reduced from £32,740 to £21,177. West Ham forms part of London which has a very considerable motor omnibus service, the unfair competition of which was commented upon several years ago by Mr. H. E. Blain, when he was Manager.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published July 9th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

*Names in italics indicate communicators of inventions from abroad.*

11,539/13. **Improved Transformers.** R. ARNO. The specification describes a method of obviating the possibility of leakage through the iron cores from the h.t. windings to the l.t. windings. The respective windings are located on separate cores, which are insulated from one another by thin sheets of mica or other material. To compensate for the increased reluctance, the section of the cores is considerably enlarged at the joints. As an additional safeguard, the cores on the l.t. side may be earthed. Fourteen figures.

13,418/13. **Reverse Power Relay.** E. G. WATERS. A safety relay, chiefly applicable to the protection of A.C. generators connected in parallel and distributing parallel feeders. The relay has two movable current coils and a fixed coil. The motion of one or other of the current coils is started by interaction with the fixed coil, but is continued by the mutual repulsion between the current coils, even if the fixed coil becomes de-energised after the movement has commenced. An article in *ELECTRICAL ENGINEERING*, June 25th, p. 369, gives details as to the method of applying this device. Six figures.

23,478/13. **Signalling System.** G. DEARLE. Either alternating or direct current may be used for the operation of this system. A series of lamps and audible signals is provided at each station, together with a battery or transformer for supplying energy. Each station is also provided with a signalling switch, the stops of which are interconnected in such a way that on moving the switch arm to the first position, all the lamps at the receiving and sending stations are caused to glow dimly. When the arm is moved to the desired signal, the lamp corresponding to this signal is short-circuited at the sending station, so that it ceases to glow, whilst the corresponding lamp and audible signal at the receiving end come into full operation. The sender has thus a positive check that his signal has been properly transmitted. Five figures.

8,185/14. **Loading Duplexed Telephone Lines.** H. B. M. PLEIJEL and A. H. OLSSON. The present practice of loading overhead lines is to employ double coils for each pair of lines. The stray fields produced are undesirable, as they give rise to eddy current losses in the metal casings, and consequent damping. When these lines are duplexed, special duplex loading coils are necessary. The above Specification describes a method of loading, whereby no extra duplex loading coils are required. The double coils for each pair of lines are enclosed in a case made of non-conducting, non-hygroscopic material, such as glass, and the coils are made of a size sufficient to produce a considerable stray field. This stray field is utilised to produce the necessary self-induction for the loading of the duplex line, so that extra loading coils are unnecessary. Owing to the coils being enclosed in non-conducting cases, the eddy current losses due to the stray fields are extremely small. Lightning arresters are fixed in each case. Three figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Distributing Systems, Cables and Wires, Insulating Materials.** &c.: SUNDERLAND [Wire rope insulator couplings] 2,790/14; VON KANDO [Insulators] 2,849/14.

**Dynamos, Motors and Transformers:** JOWERS [Motor control] 16,167/13; BRIT. ELECT. TRANSFORMER CO. and CROSBIE HILL [Phase transformer] 19,182/13.

**Electrometallurgy and Electrochemistry:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Composite metals] 19,021/13; RENNERFELT [Furnaces] 24,850/13; LESCURE [Furnace] 3,291/14; SOC. ELECTRO-METALLURGIQUE DE ST. BERON [Furnaces] 3,835/14; A.E.G. [Welding machines] 8,595/14; GES. FÜR ELEKTRO-OSMOSE [Electro-osmotic diaphragm] 9,265/14; ASHCROFT [Manufacture of alkali metals] 10,980/14.

**Heating and Cooking:** BERRY [Heating apparatus] 14,699/13; DE KOK [Water heaters] 16,214/13; SIEMENS SCHUCKERTWERKE GES. [Cooking ranges] 29,714/13.

**Ignition:** JOHNSON [Sparking plugs] 16,078/13; POHL ES FIAT [Ignition apparatus] 20,800/13; R. BOSCH [Interrupter] 10,380/14.

**Incandescent Lamps:** BOARDMAN, BOARDMAN & BOARDMAN [Daylight-effect lamps] 14,760/13; KRUGER [Filaments] 16,066/13.

**Instruments and Meters:** KOLSTER [Decrement meter] 3,478/14; GRISSON [Röntgen ray meter] 8,146/14.

**Storage Batteries:** SVENSKA AKKUMULATOR AKTIEBOLAGET JUNGNER [Electrodes] 38/14.

**Switchgear, Fuses and Fittings:** PEARD [Fuses] 19,104/13; BICKERSTAFF [Switches] 22,798/13.

**Telephony and Telegraphy:** THOMPSON (*Cie. Univ. de Telegraphie et de Telephonie sans Fil*) [Wave-producing apparatus] 14,140/13; AITKEN [Telephone systems] 14,524/13; LONG [Coin freed telephone] 20,126/13; VISCA [Telegraph transmitters] 26,570/13; WESTERN ELECT. Co. (*Woodward*) [Telephone switching apparatus] 28,802/13.

**Traction:** FINDLAY & FINDLAY [Train control] 14,532/13; MUTTON [Railway signals] 14,771/13.

**Miscellaneous:** A.E.G. [Soldering apparatus] 14,518/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos, Motors, and Transformers:** HEYLAND [Polyphase machinery] 12,282/14; VOIGT & HAEFFNER AKT. GES. [Regulation of A.C. generators] 14,380/14.

**Telephony and Telegraphy:** SIEMENS & HALSKE AKT. GES. [Automatic and semi-automatic telephony] 6,628/14.

**Switchgear, Fuses, and Fittings:** COLAS [Contact apparatus] 14,006/14; HENSELL [Fuses] 14,474/14.

**Miscellaneous:** SIEMENS-SCHUCKERTWERKE GES. [Hand-drilling machines] 14,022/14; HARLÉ ET CIE. [Distant control] 14,461/14.

The following Amended Specification may now be obtained:—

**Storage Batteries:** F. SABLON [Accumulator case] 6,066/13.

### Restoration of Lapsed Patent

4,030/08. **Improved Telegraph Poles.** An order has been made, restoring this Patent to F. H. TIDNAM on July 1st, 1914.

### Opposition to Grant of Patents

25,902/12. **Treatment of Magnetic Steel.** B.T.-H. Co. (*G.E. Co., U.S.A.*).

26,800/12. **Manufacture of Ductile Tungsten.** C. TRENZEN. The grant of these two Patents has been allowed by the Comptroller.

1,862/13. **Earthing Clip.** F. TOWNSON. The grant of this Patent has been allowed by the law officer.

### Amendment

9,426/12. **Interrupters.** J. BIJUR. As a result of extended investigation under Sect. 8, this Specification has been amended by way of disclaimer.

### Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

13,036/00. **Field Windings of Dynamos and Motors.** H. F. JOEL. This invention applies to machines having an even number of field magnet poles. It describes a method of construction by which all the poles can be magnetised to the correct polarity by the use of a single sinuous coil. This coil is wound on a special former, and the frame of the machine is made in two halves, which can be taken apart to allow the coil to be placed in position, so that the winding passes round three sides of each polar extension. In addition to the obvious advantage of simplicity of construction, this method of winding conduces to sparkless commutation. Twenty figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** E. C. R. MARKS (*Soc. Anon. Italiano Gio Ansaldo & Co.*) [Motor control] 6,461/08; M. KALLMANN [Motor control] 6,957/09.

**Dynamos, Motors and Transformers:** SIEMENS BROS. & Co. and C. RIBER and H. IRELAND [Drive for dynamo] 6,877/09.

**Incandescent Lamps:** DEUTSCHE GASGLÜHLICHT AKT. GES. [Filament manufacture] 28,775/06; W. HEINRICH [Tungsten filaments] 7,092/09.

**Instruments and Meters, &c.:** J. H. BOWDEN and A. H. JACKS [Prepayment meter] 7,005/09.

**Switchgear, Fuses, and Fittings:** SIEMENS BROS. & Co. (*Siemens & Halske Akt. Ges.*) [Mercury switches] 6,073/05, 25,962/09; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Electrolyte for lightning arrester] 6,872/09; J. E. LIDDLE [Liquid starters] 21,595/09.

**Telephony and Telegraphy:** SIEMENS BROS. & Co. (*Siemens & Halske Akt. Ges.*) [Printing telegraphs] 6,740/03, 4,813/06; SIEMENS & HALSKE AKT. GES. [System of telegraphy] 6,929/07.

**Traction:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Signalling] 6,985/09.

**Miscellaneous:** G. H. OATWAY [Device for testing fire-alarm apparatus] 5,984/01; J. M. CAGE [Submarine equipment] 7,179/06; T. H. WURMB [Alarm thermometer] 7,127/07; W. J. GILLILAND and J. E. PLANT [Regulator for hot water system] 6,846/08.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 413. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**SPEED COUNTERS.**—A series of five different designs of speed counters are put forward in a new leaflet from the General Electric Co. (67 Queen Victoria Street, E.C.), including convenient hand instruments for pressing against the ends of revolving shafts, and one provided with a friction wheel by which the speed of any surface in feet per minute can be determined.

**ELECTRICAL PLANT.**—A new edition of the General Electric Co.'s Bulletin, entitled "Important Plant," contains many excellent illustrations of the Witton Works and its products, including turbo-generators, large continuous-current dynamos, rolling mill and other motors, alternators, rotary converters, motor installations, switchboards, &c.

**ELECTRICAL SUPPLIES.**—Some G.E.C. leaflets are also to hand, showing the latest patterns of a number of different specialities which are manufactured by the company. One of the illustrations shows the mining type of "Salford" circuit breaker, which is similar in construction to that described in these columns last week. The "D.B." switch and cut-out sets, the "Slick" combined switch and wall plug, and various patterns of lamp-holders adapted to meet the varied needs of present-day practice are also dealt with. A new and very neat type of suspension switch, with the casing composed of non-inflammable imitation ivory, deserves special mention. The Universal grinders and polishing machines, which can be run from any existing electric light circuit, the "Peel Conner" table telephone sets, and the G.E.C. ammeters and voltmeters are sufficiently well known to require no lengthy description.

**SWITCHGEAR, FITTINGS, &c.**—Further additions to the catalogues of the General Electric Co. are the leaflets which we have received, dealing with "Leader" and "Twin Break" switches and fuses. The former type are supplied in teak cases, and are suitable for circuits up to 250 volts; whilst the latter have cast-iron cases, and are for circuits up to 500 volts. Some new plug adapters and other electric light fittings of improved construction, a handy little bench drill and a small portable drill, fitted with adapters and ready for immediate connection to any lamp-socket, are also included in these lists. We note that the prices of a number of the above specialities have been reduced.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**CIRCUIT BREAKERS.**—The latest patterns of B.T.-H. automatic circuit breakers with magnetic blow-out are described in a new leaflet from the British Thomson-Houston Co., Ltd. (Rugby).

**CARBON LAMPS.**—A new catalogue of carbon filament lamps has been issued by Pope's Electric Lamp Co., Ltd. (Hythe Road, Willesden, N.W.), and will be sent on request to any trade friends of the company who have not yet received a copy. A large number of standard and special lamps for lighting are included, as well as radiator lamps and "lamps" for resistance purposes.

**AUTOMATIC FURNACE.**—A booklet from Clyde Evaporators, Ltd. (90 Mitchell Street, Glasgow) describes an improved type of furnace combined with automatic stoker, which we understand has been installed by them with considerable success in several boiler plants in Scotland. The furnace, which is applicable to all classes of boilers, is of "V" section, and the fuel is fed in by horizontal screws mounted on each side of the flue. The firebars form the sides of the V, so that the ash from the consumed coal falls to the bottom, and is forced to the front of the boiler by the ash screw. Forced draught is employed, to ensure a sufficient supply of air. Some of the advantages claimed for this furnace are complete combustion of fuel, and decreased coal consumption for same evaporation. Full particulars may be obtained on application to the makers.

**ALUMINIUM.**—A useful sheet from the British Aluminium Co. (109 Queen Victoria Street, E.C.) gives detailed weights,

dimensions, &c., of standard aluminium tubes, bars, strips, sheets, wires, &c.

**CRANE MOTORS.**—Full particulars of the special line of continuous-current motors which the British Thomson-Houston Co., Ltd. (Rugby), have developed for crane work are contained in an illustrated pamphlet.

**PORCELAIN INSULATORS.**—Another B.T.-H. pamphlet deals with a great variety of designs of porcelain insulators.

### HALF-WATT LAMPS FOR STATION LIGHTING

WE reproduce here two photographs which have been sent us by Siemens Bros. Dynamo Works, Ltd. (Tyssen Street, Dalston), one showing the exterior, and another

FIG. 1.—STATION ENTRANCE LIGHTED BY HALF-WATT LAMPS.

certain platforms of a London terminus where Wotan half-watt lamps have been applied for lighting. The photographs

FIG. 2.—STATION PLATFORMS LIGHTED BY HALF-WATT LAMPS.

were taken about midnight, and have not been retouched. These lamps are of 1,000 c.p. running two in series on a 200-volt circuit, and are being used to replace a portion of

the arc lighting. The existing arc-lamp fittings have been converted for use with half-watt lamps in order to keep a uniformity of fitting, and it is quite probable that further circuits will be rearranged in a similar manner in the near future.

### A NEW "INTERMEDIATE" TUMBLER SWITCH

**A**N IMPROVED pattern of 10-ampere "pivot intermediate" tumbler switch has been introduced by A. P. Lundberg & Sons (477-489 Liverpool Road, London, N.), and is illustrated here. The main improvement consists in the substitution of knife-blade and double-spring-clip contacts for the original face contacts, in the elimination of the porcelain rocker, and in the use of a vitreous porcelain base, and of mica insulation on the moving part. The switch may be fitted with either brass or porcelain cover, and its dimensions are as follows:—Diameter of base,  $3\frac{1}{2}$  in., overall projection,  $3\frac{3}{8}$  in. The action of the switch is exceptionally "clean" and easy. The current-carrying parts are well sunk in the base, and provision is made for the attachment of an earthing

NEW PATTERN OF PIVOT INTERMEDIATE SWITCH.

wire. Although primarily intended for use on two-way intermediate circuits controlling large numbers of lamps, the switch has many other uses, and by slight modifications may be converted into any one of the following types:—single-way, 20-ampere capacity; single-way with quadruple break; double-pole; two-way with definite gap in passing over; pilot; reversing; series-parallel; all-or-part. The last three modifications differ from the ordinary patterns of these types in having no "off" position. Some of these switches are extensively used for the control of heating apparatus and small motors, and others for certain of the lighting controls dealt with in the firm's well-known publication "Lektrik Lighting Connections." The reversing switch adaptation will be found much more convenient than some of the ancient forms still used in laboratory, testing, and other special apparatus.

### ALUMINIUM

**I**N order to dispose finally of the impression which was once common that the substitution of aluminium for copper as an electrical conductor was not justified on grounds of economy, the British Aluminium Co., Ltd. (109 Queen Victoria Street, E.C.), have issued a very attractive illustrated booklet entitled "Power, Its Economical Distribution." The economics of the subject are carefully gone into, and the saving obtained by the substitution of aluminium for copper is shown for various prices of both metals. The important question of scrap value is then discussed, and the favourable position of aluminium in this respect is shown. Coming, then, to matters of detail, the rating of aluminium low-tension cables is treated in reference to the regulations existing in various countries. Particulars of aluminium cables with vulcanised bitumen, paper and rubber insulation, are given in useful tabular form, and a good deal of information on high-tension cables also appears. One of the most interesting sections is that devoted to jointing, where several kinds of mechanical connectors for stepped joints are described. The work throughout is copiously illustrated with actual examples of transmission lines, cables, and joints, and some charming views of the Company's works at Kinlochleven.

### HALF WATT LAMPS AT LEEDS

**W**E have received from the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), the illustration given here of Leeds City Square, which is now lighted by sixteen 500-watt 100-volt Mazda half-watt

CITY SQUARE, LEEDS, LIGHTED BY HALF-WATT LAMPS.

lamps, in the ornamental lanterns formerly used for the 750-watt arc lamps. The illumination is very intense and well distributed, and not only has the cost of current been reduced to two-thirds, but considerable saving in cost of maintenance has been effected.

### WATER SOFTENING

**A** PARTY of engineers visited the Hooton Water Works, Cheshire, recently, to inspect the "Permutit" water-softening plant, which is the first of its kind at a public water-works in this country. The water treated has an initial hardness of about  $19^{\circ}$  Clarke. The Company are bound by Act of Parliament to supply water at  $10^{\circ}$  of hardness, and after investigation of various systems of water-softening, it was resolved to instal the "Permutit" system, which is largely used in Germany. The process is based on an exchange of the calcium and magnesium salts which form the hardness of the water, for the sodium, which is the replaceable base in the "Permutit." This exchange is spontaneously effected immediately the water is passed through a layer of the material, the water going in at the top and issuing from the bottom completely softened. The "Permutit" is insoluble in water, and undergoes no visible change. It is capable of being regenerated over and over again by the simple application of a solution of common salt, which expels the lime and magnesia from combination and reinstates the sodium. This operation is carried out with the aid of two large ferro-concrete tanks, from which the salt solution is allowed to flow through the filters for twelve hours in the case of each battery alternately. The capacity of the plant is one million gallons daily. This water, which is softened to zero, is mixed with an equal quantity of hard water at  $19^{\circ}$ , the resulting two million gallons being sent to the mains with a hardness of  $9\frac{1}{2}^{\circ}$ . No precipitate or sludge is formed at any stage of the process, and the entire plant is looked after by two men.

**An American Electrical Engineering Handbook.**—A handbook of 356 pages, got up in the convenient style of the larger engineering pocket-books, is being issued by the Julian d'Este Co. (Boston, U.S.A.), and forms the electrical appendix to the d'Este Steam Engineer's Manual. A concise introduction deals with general matters and steam plant, while the main electrical portion of the work, by Mr. C. Penrose, deals in a practical way with testing and measurements, dynamos, motors, transformers, &c., pyrometry and photometry. A number of illustrations are given of types of electrical plant and typical American generating stations, and there are interesting notes on modern power-house and transmission-line equipment.

**Electric Charging for Commercial Vehicles.**—The County of London Electric Supply Co. are now prepared to charge electric vehicle batteries at their City Road station, and facilities have been provided for the drawing in and standing of the vans in question. All inquiries as to rates should be addressed to their head office, Moorgate Court, Moorgate Place, E.C.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Aldershot.**—Natural draught cooling tower, chimney type. Borough Electrical Engineer. August 4th.

**Ashton-under-Lyne.**—Meters, motors, motor starters, and arc-lamp carbons. Borough Electrical Engineer. July 29th.

**Australia.**—The Deputy Postmaster-General, Perth, requires a supply of switchboard parts, also portable telephones, common battery telephones, &c. Further particulars, 72 Victoria Street, S.W., or 73 Basinghall Street, E.C.

**Burton-on-Trent.**—An expenditure of £7,000 is to be incurred for extensions at the power-station. The Local Government Board has sanctioned this expenditure without ordering an inquiry, a fact which has caused some satisfaction among the members of the Electricity Committee as indicating the Board's satisfaction with the manner in which the undertaking is carried on.

**Dublin.**—A Local Government Board inquiry was held last week concerning a loan of £82,000, of which £5,000 is for the conversion of public gas-lamps to electric lighting.

**Grimsby.**—One 790 ampere-hour battery, hand-regulated reversible booster, and switchgear. Borough Electrical Engineer. July 23rd.

**Holmfirth.**—The L.G.B. has expressed its general satisfaction with the electric light scheme recently put forward.

**Manchester.**—Sub-station switchgear (6,600 volts) and fuse boxes. Chief Electrical Engineer. July 24th.

**Oldham.**—In consequence of the illness of Mr. S. W. Newington, the Borough Electrical Engineer, the Council has had to call in Mr. Robert Blackmore, of Stalybridge, who has prepared an extension scheme involving an expenditure of £40,000.

**Redditch.**—The Local Government Board has given the Corporation permission to obtain tenders for the new plant under the £18,000 scheme of extensions recently inquired into. Sanction to the loan, however, has not been granted, pending the necessary receipt of further details from the Engineer.

**South Africa.**—The East London Council proposes to borrow £775 for extensions to switchgear, transformers, &c.

**Turton.**—Overhead and underground cables. Borough Electrical Engineer. July 23rd.

**Warrington.**—Extra high-tension and low-tension switchboard feeder panels. Borough Electrical Engineer. July 21st.

### Wiring

**Basingstoke.**—Tenders are to be obtained for wiring the town hall.

**Southampton.**—Wiring of Farm Institute, Sparsholt. Clerk to County Council. (See advertisement on another page.)

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Barnsley.**—New town hall.

**Batley.**—Police court and station.

**Birmingham.**—Large scheme of asylum extensions (£130,000).

**Bradford.**—Cinematograph theatre.

**Brighton.**—Hostel for women students (£10,000). Education Committee.

**Dundee.**—Children's hospital.

**Guildford.**—New municipal offices.

**Ilkley.**—Cinematograph theatre.

**Liverpool.**—Extensions by Mersey Docks and Harbour Board (£226,500).

**South Shields.**—Theatre. Architect, R. H. Moreton.

**Torquay.**—New tuberculosis hospital.

**Wallasey.**—New secondary school.

**Wellington.**—New Council offices.

**Yarmouth.**—Elementary school.

### Miscellaneous

**Salford.**—Street flame arc lamps and lowering gear. Borough Electrical Engineer. (See advertisement on another page.)

**South Africa.**—The East London Council proposes to borrow £7,814 for tramway extensions.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Bristol.**—The Bristol Tramways & Carriage Co. has placed a contract for carbon-filament lamps with Siemens Bros. Dynamo Works.

**Crook.**—A tender for public lighting has been submitted by the Newcastle-on-Tyne Electric Supply Co. The price offered is 30s. per lamp per season for current, with a further 5s. 4d. per lamp for maintenance. If the Company is to do the switching on and switching off, an additional 11s. per lamp is quoted, making a total charge of 46s. 4d., as against the present charge of 45s. by the local gas company. The Council must also bear the expenditure on services from the cable to the lamp, and the conversion of the existing gas lamps.

**Dartford.**—The tender of Messrs. Fraser & Chalmers for a 1,000-kw. turbo-alternator, transformer, condenser, &c., at £4,554 has been accepted.

**Darwen.**—The following tenders have been accepted for two trams: Bodies, The United Electric Car Co.; electrical equipment, Dick, Kerr & Co.; trucks, The Brush Electrical Engineering Co.

**London: L.C.C.**—In October last year the Council accepted a tender by the Cedes Electric Traction Co. to supply a petrol-electric chassis for a fire escape van, at £890, delivery to be made by June 14th, 1914. The Fire Brigade Committee now reports that although the contract time has passed, very little progress has been made with manufacture of the chassis, and in consequence it recommends that the clause enabling the Council to determine the contract be put into force. It is also recommended that an offer of Leyland Motors, Ltd., to supply an escape van similar to eleven other vans now on order from the Company at £641 10s. be accepted instead.

The Great Northern Railway Co. has accepted the tender of Siemens Bros. Dynamo Works for a twelve months' supply of carbon-filament lamps and station lighting reflectors.

**Manchester.**—The alternator in the turbo-generator for Stuart Street, mentioned on page 403 of our last issue, is to be supplied by Siemens Brothers Dynamo Works and will have a continuous output of 6250 kw. at 3000 r.p.m.

**Sheffield.**—The tender of Messrs. John Walsh, Ltd., for wiring the workhouse buildings at £105 has been accepted.

**Stratford.**—The following tenders have been accepted:—Lighting battery, the Tudor Accumulator Co.; booster, Lancashire Dynamo & Motor Co.; switchboard, B. Thomas.

**York.**—The annual contract for carbon-filament lamps, radiator lamps, tantalum lamps, and tantalum traction lamps, has been placed by the Corporation with Siemens Bros. Dynamo Works.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £63 5s. to £63 15s. (Last week, £63 10s. to £64.)

**Reduction in Cable Prices.**—W. T. Henley's Telegraph Works Co., Ltd., announce reductions in the prices of rubber-insulated wires and cables which will have the effect of increasing the trade discounts on C.M.A. and Association flexibles to 33½, 15, and 10 per cent. respectively for the 2,500, 600, and 300 megohm grades; 25 per cent. for the 600 megohm non-Association cable, and 10, 15, and 10 per cent. for pure I.R. cable. Special prices are quoted at £8 5s. per mile per 1/18, and £7 15s. for 3/22 non-Association Class W. cable. Reduction have also been made in the prices of materials for the Henley wiring system, the discount for cables being 40 per cent. and for accessories 33½ per cent. The discounts on rubber-sheathed cables have been reduced to 17½, 15, and 10 per cent.

The Liverpool Electric Cable Co. have reduced discounts to the following figures: "Association Quality," 50 and 10 per cent.; Non-Association Quality, 50, 10, and 5 per cent. for sizes up to 7/16, and 50, 10, and 2½ for all larger sizes. Special net prices of £8 per mile for 1/18 and £9 10s. for 3/22 non-Association taped and braided cables are also quoted.

**Works Holidays.**—The works of the Midland Electric Manufacturing Co., Ltd. (Rea Street South, Birmingham), will be closed from Friday evening, July 31st, till Monday morning, August 10th.

**Works Outing.**—The Linolite Co. (25 Victoria Street, Westminster) had their outing on Saturday, the 4th inst., at Herne Bay. Mr. A. S. E. Ackermann, the Co.'s Engineer and Manager, and Mr. R. L. Matthews, the Assistant Manager, were both present.

**Bankruptcies.**—A Receiving Order has been made against Granville Burgess, 27 Museum Chambers, Bury Street, W.C. The first meeting of creditors will be held at Bankruptcy Buildings, Carey Street, on July 23rd at 11 a.m., and the public examination will take place at the same address on August 25th, at 11 a.m.

### LOCAL NOTES

**Dover: Bulk Supply.**—A draft agreement for a bulk-supply of electricity to the Corporation has been submitted by the Engineers of the South-East Kent Electric Power Co. The Borough Electrical Engineer suggested that the Committee should look into the agreement and see how far the prices would compare with the Corporation's present prices. He made a comparison two or three years ago, and did not think the price mentioned then would tempt the Corporation to take a supply of electricity in bulk.

**London: L.C.C.: Greenwich Generating Station.**—The work of repairing the turbo-generator, the insulation of which broke down in January this year, was entrusted to the makers, the British Westinghouse Co. The Highways Committee now states that the cost amounted to £1,615 16s., and that the repairs necessitated the renewal of the whole insulation at one end of the machine. This figure, however, includes £80 as the cost of certain spare windings which were found to be required.

**Loughborough: Position of Electricity Undertaking.**—In reporting a net profit of only £74 on the past year's working, the Chairman of the Electricity Committee confessed that he had hoped for a better result. The Department, however, he said, had been hit rather badly in the matter of coal, as no contract existed at the time of the strike. There had also been increased expenditure in other directions, but taking into consideration the fact that their plant needed extension to meet with the demand, the position was not one to be complained of. At the same time a considerable increase in revenue was necessary in the future.

**Luton: Distribution of Electricity Profits.**—The net profit on the electricity undertaking last year amounted to £4,793, and the Electricity Committee recommends that no portion of this shall be allocated to relief of rates. The sum of £1,000 is to be used for meeting capital expenditure, which the L.G.B. suggests should be paid for out of revenue, and after meeting one or two other items, such as renewal of valves and liners of engine, and the bonus to staff, the remainder is to be retained as working balance. There was considerable discussion upon these recommendations, but the Committee's proposals were finally passed by a narrow majority.

**Manchester.**—A Local Government Board inquiry was held last week concerning a loan of £68,000 for extensions in connection with the electricity undertaking. Some discussion took place during the inquiry upon remarks made by the inspector concerning an item of £10,000 for motors, which, the inspector suggested, should be paid out of revenue, as was done by many smaller local authorities. Mr. Hooper emphasised this point, and added that there was no object in borrowing money for capital purposes whilst at the same time the Corporation was contributing large sums from the electricity profits to relief of rates. It was, he said, a national question, and for the benefit of the whole community, that the cheapest possible power should be obtainable. There was no opposition to the loan.

**Sheffield: Use of Renewals Fund.**—A proposal by the Electric Supply Committee to pay the cost of two cooling towers now under construction, viz., £2,800, out of renewals fund was briefly discussed at the last meeting of the Corporation. A recommendation to refer the matter back for further consideration was carried.

**Progress of Electricity Undertaking.**—At the last meeting of the Corporation, Alderman Styring called attention to the fact that no less than £297,239 had been paid into the sinking-fund since the electricity undertaking had started, and as the total cost of the undertaking when purchased

was £308,608, this must be considered to be a very satisfactory result. This statement apparently seemed to move a number of Councillors to ask for concessions in the matter of price to various classes of users, including power users, publicans, and large shopkeepers, matters which will be taken into consideration by the Committee.

**Wimbledon: Electricity Accounts.**—There was a net profit of £3,471 on the working of the electricity undertaking last year, after meeting capital charges.

### APPOINTMENTS AND PERSONAL NOTES

We regret to record the death of Mr. S. W. Newington, who had been Borough Electrical Engineer at Oldham for the past twenty-one years, since the opening of the municipal electricity works there.

Mr. E. J. B. Lowdon, of Lowdon Bros. & Co., Dundee, has been elected President of the Electrical Contractors' Association of Scotland.

Mr. D. Neill-Keith has been appointed Switchboard Representative for Ferranti, Ltd., for the Lancashire District and Ireland.

The salary of Mr. C. W. Salt, Borough Electrical Engineer at Torquay, is to be increased from £350 to £450 by two annual increments of £50 each. On this understanding Mr. Salt waives any right to fees for capital works, and also agrees to remain with the Corporation until the contemplated extensions are completed.

The salary of Mr. H. E. Annett, Station Engineer to the Bolton Corporation, is to be increased to £250 per annum on his appointment as Resident Engineer at the new Back-o'-th'-Bank Station of the Corporation.

A recommendation by the Bath Electric Lighting Committee to increase the salary of Mr. F. Teague from £550 to £600 per annum has been carried in the Council by a majority of three votes, after a considerable debate.

An Assistant Lecturer is required in the Electrical Engineering Department of the Birmingham Municipal Technical School. Commencing salary £150 per annum. Applications to the Secretary by August 1st.

A Lecturer in Electrical Engineering is required at the East London College. Applications to Professor J. T. Morris by July 28th.

An Assistant Mains Superintendent is required at Derby. Salary £150 per annum. (See advertisement on another page.)

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Barcelona Traction, Light & Power Co.**—An offer has been made of £3,118,060 five per cent. first mortgage 50-year bonds at 82½. The Company owns or controls a large number of electric supply and traction undertakings, including the important Ebro Power Co., which will shortly complete a 152,000 h.p. equipment.

**Nairobi Electric Power & Lighting Co.**—At the annual meeting last week it was stated that the directors have under consideration a scheme for utilising some waterfalls on the Thika River which will give a minimum of 2,000 h.p. in the driest season. A new plant of 750 kw. will be laid down to deal with this. Mr. E. W. Monkhouse will probably visit Nairobi before a final decision is come to.

**Victoria Falls & Transvaal Power Co.**—Speaking at the annual meeting last week, when the report and accounts given in our issue for June 25th, page 378, were adopted, the Marquis of Winchester said that the Company had been hit during the past year by drought and labour troubles, and that, taking into consideration these facts, the past twelve months need not be viewed with any apprehension as to the future prosperity of the Company.

**Crompton & Co.**—At the annual meeting on Tuesday, the report and accounts given in our last issue were adopted. Mr. C. F. Tufnell, Chairman of the Company, in commenting upon the improved position of the Company under the new régime, said that not only was the business of the Company on a much sounder footing than formerly, but that in his opinion this remark would apply to the electrical trade as a whole, and he thought there was not much likelihood of a return of the insensate price cutting which prevailed in former years. The financial position was such that a more liberal distribution might have been made of the available surplus, but the directors felt the need for a conservative policy from the commencement.

## SUMMARY

NOTES on the arrangements for the next session at some of the Universities and Technical Colleges are given on page 416.

A SCHEME for the establishment of a central testing Institution or National Electrical Proving House has been proposed. (Page 416.)

SOME interesting information, from German sources, about half-watt lamps is published on page 417.

SOME particulars are given of the measures taken to re-establish the supply after the flooding of Messrs. Spiers and Pond's generating plant in connection with the fire at their premises. (Page 417.)

THE system of pre-heating the air supplied to boiler furnaces has been in use for some time on a B. & W. marine type boiler at Poplar Electricity Works. Some particulars of the plant are given. (Page 418.)

SOME notes are given on the electrical installation at a hospital in Glasgow. (Page 418.)

A NEW omnibus driven by accumulators is described. (Page 418.)

THE use of a series multiplying resistance with a hot-wire voltmeter is discussed in our Questions and Answers columns. (Page 419.)

SOME of the Specifications published last week relate to wireless telegraphy, manufacture of lap-welded tubing, and tungsten filaments.—The Comptroller has

allowed the grant of one of the B.T.-H. Co.'s Patents for the manufacture of tungsten. (Page 420.)

AMONG the papers at the Congress of the Tramways and Light Railways Association was one by Mr. H. M. Sayers on "Tramway Experiences in Brazil." Mr. F. Bland and Mr. R. Humphries also read Papers on "Standard Tramway Rails" and "Rail Joints." (Page 421.)

As a protest against recent happenings, the Chairman and Managing Director of Marconi's Wireless Telegraph Co. resigned at the annual meeting this week, but were re-elected.—A Committee has been formed to consider the organisation of the telegraph service. (Page 421.)

HALF-WATT lamps are now obtainable in this country down to 500-watt sizes for 200 to 255 volts. Other new sizes are 200 and 300 watts at 100 to 130 volts, and 100 and 200 watts at 50 to 65 volts. A new projector lamp is also being introduced. Full details and illustrations of various makes, as well as an indication of the next sizes to be expected, appears on pp. 422-424.

EXPENDITURES are contemplated at Dublin (£80,300); Edinburgh (£220,000); Grimsby; Islington (£5,316); and Walsall.—Electric lighting schemes are under consideration at Blackrock and Hayle.—Cable is required in Rochdale; Australia; submarine cable in Canada; electric motors in South Africa; and an electrical equipment for a mint in China. (Page 425.)

THE Surbiton electricity undertaking, which is at present worked by Messrs. Callender's, is to be transferred to them completely.—A number of municipal electricity accounts for the past year show exceedingly satisfactory results. A feature of them is the large sums paid out of revenue for works of a capital nature.—The Bristol undertaking has increased its output by 50 per cent. during the past two years.—An electrical section of the Chamber of Commerce is to be formed at Blackburn. (Page 426.)

**Electric Power at a Cement Works.**—A party of members of the Junior Institution of Engineers paid a visit last Saturday afternoon to the Tunnel Cement Works, Purfleet. The party were shown the chalk quarry, the mills, and the two large rotary kilns, each 210 ft. long, and the power station, which contains a 1,200-kw. turbo-alternator of the A.E.G. impulse type, with a steam consumption of 13·8 lb. per kw-hr. on full load, with a cooling water supply of five gallons per lb. of steam. The motors have been assembled in special motor rooms, so that they are in a large measure protected from dust. Open type motors are used, with special insulation and dust-proof bearings. The switchgear is of a most substantial type throughout, all motors being provided with oil-immersed controller type starters with self-contained resistances. The smaller motors are fitted with air circuit-breakers in dust-proof cast-iron cases, and the larger machines with sheet-iron switch pillars containing oil switches.

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE full course in Electrical Engineering at the University of Birmingham extends over four years, and qualifies for the degree of B.Sc. Sir Oliver Lodge is Principal, and the Electrical Engineering Department is presided over by Prof. Gisbert Kapp. Mr. E. J. Kipps and Dr. T. F. Wall are lecturers in Electrical Engineering. The next session begins on October 6th, and full particulars of the courses can be obtained from the Secretary.

The session for 1914-15 at the University of Liverpool will begin on October 8th. The Electrical Engineering Section of the Faculty of Engineering is under Prof. E. W. Marchant, and lectures in Municipal Electrical Engineering are given by Mr. A. Bromley Holmes. The prospectus may be obtained from Mr. E. Carey, Registrar.

At the Electrical Engineering Department of the City and Guilds (Engineering) College, Imperial College of Science and Technology, South Kensington, which is under the direction of Prof. T. Mather, F.R.S., complete courses are given leading up to and including the highest specialised instruction for students, with the object of fitting them to take leading positions as electrical engineers, scientific advisers, investigators, or experts, and for those already qualified who desire to take up more advanced training and research. Further information may be obtained from the Registrar.

The next entrance examination at the City and Guilds Technical College, Finsbury, will be held on September 22nd. The instruction at this College, of which Prof. Silvanus P. Thompson is Principal, is adapted to various classes of students, including those from secondary schools who desire to receive practical and scientific training bearing on their future work, and those who have already had experience in works and require a more systematic training in electrical engineering science. Particulars can be obtained from the Registrar, Leonard Street, Finsbury, E.C.

The next session at the Armstrong College, Newcastle-on-Tyne (University of Durham), the Electrical Engineering Department of which is under Dr. W. M. Thornton, will commence on September 28th. Full particulars can be obtained from Mr. F. H. Pruen, Secretary.

The next session at the Manchester Municipal School of Technology (University of Manchester) will open on October 6th. Courses are arranged leading to degrees in the Electrical Engineering Department of the Faculty of Technology.

A course of instruction in Electrical Measurement and Practical Electricity, by Dr. E. Taylor Jones, Professor of

Physics, and Mr. W. E. Williams, Assistant Lecturer in Electrical Engineering, is given at the University College of North Wales, Bangor. For prospectus apply to Mr. J. E. Lloyd, Secretary.

Theoretical and practical training in all branches of Electrical Engineering is given under Prof. W. Robinson at University College, Nottingham. The three years' course prepares for the London B.Sc. degree. The next session commences September 28th. Particulars can be obtained from the Registrar, Dr. J. D. Black.

Among the examination results at the University of Bristol in the Faculty of Engineering are the following:—Examination for the degree of M.Sc. (Pass), R. A. Bruce and A. J. S. Pippard. Final examination for degree of B.Sc. (Electrical Engineering) Pass:—N. J. Rose, E. L. Sainsbury, and J. A. Smale.

## A PROPOSED ELECTRICAL PROVING HOUSE

IN view of recent discussion of the necessity for electrical goods for Canada complying with the code of the Chicago Board of Underwriters, Mr. C. H. Wordingham sends us a copy of a long letter which he addressed last year to the Institution of Electrical Engineers. Now that the Industrial Committee has been abolished, permission has been given for the contents of the letter to be published. Mr. Wordingham urges the desirability of founding a central Testing Institution, to be called the National Electrical Proving House, where tests could be made of types of apparatus for compliance with such regulations not only for goods to be exported to Canada, but with standards to be set up by the British electrical industry. He proposes that the Proving House should not draw up these rules, but that as regards articles for use in consumers' installations, this should be done by the Institution of Electrical Engineers, while detailed specifications should continue to be formulated by the Engineering Standards Committee, and experimental investigations conducted by the National Physical Laboratory. The Proving House should aim at testing types of apparatus rather than every individual article. The control should be vested in a council including representatives of Government departments and the various electrical interests, and the work should be under the direction of an engineer of high standing. In the early stages of the work the Proving House would have to be subsidised by the various interests concerned, but later on the money received in fees would probably render it self-supporting. A reference to the existing arrangements in this connection is made on page 417.

Reduced Prices and New Sizes of Half-Watt Lamps were announced on Monday.

## RECENT INVESTIGATIONS WITH HALF-WATT LAMPS

A SMALL treatise on the "Nitra" lamp by Dr. K. Mey, recently published in Germany by the *Allgemeine Elektrizitäts Gesellschaft* gives some interesting details of the development of the half-watt lamp. After stating that the limit of efficiency of the tungsten lamp should be about 0.2 watt per candle when the temperature of the filament would reach  $2900^{\circ}\text{C}$ ., the melting point of the metal, the author points out that the obstacle to attaining a temperature approaching this is the disintegration of the filament. This disintegration is not due to any electrical cause, but purely to the volatilisation or flying off of the rapidly oscillating tungsten molecules. Filling the globe with an inert gas to prevent this volatilisation had been tried years ago without success in the case of carbon filament lamps, and it was at first not expected that it would give any better result with tungsten filaments. As we have stated in previous articles, it was not successful with the ordinary straight filaments, as the energy lost by conduction and convection counteracted the gain in efficiency due to the high temperature of the filament, but by winding the filament into a spiral and by confining it to a small space with a small surface exposed to the gas, the heat transference was reduced sufficiently to make the introduction of the gas worth while. There is still a certain amount of disintegration and this, of course, affects the low candle-power lamps with filaments of only 1/50 mm. diameter to a much larger degree than the high-candle-power lamps with filaments of 1/8 mm., as the disintegrated layer in a given period is a much larger proportion of the whole in the former case. The lamps are filled with nitrogen at a pressure of about two-thirds of an atmosphere in order that the pressure shall not be great enough when hot to burst the globe.

The "efficiency" of the half-watt lamps is now expressed in watts per hemi-spherical (Hefner) candle power, the figure being 0.5 watt exactly. The average spherical "efficiency" is about 0.65 watt per Hefner candle, as compared with the figure of 1.4 watt/candle for the ordinary tungsten lamp. The spiral of a 1000 candle power lamp (110 volt) has a length of about 14.5 cm. and a diameter of about 0.62 mm., so that the surface candle-power works out at about 10.7 Hefner Candles per square mm. Experiments have proved that the candle-power decreases about 20 per cent. after the first 80 hours of burning. Dr. Mey estimates the temperature of the half-watt lamp filament at  $2400^{\circ}\text{C}$ . or  $300^{\circ}\text{C}$ . above that of the ordinary tungsten lamp filament when working at one watt per candle. The light of the half-watt lamp is consequently much whiter and nearer daylight than that of the ordinary tungsten lamp.

Some highly interesting experiments on the absolute light efficiency of the half-watt lamp were described by Dr. H. Lux in the *Elektrotechnische Zeitschrift* of May 28th. These experiments showed that the percentage of emitted radiant energy (heat and light rays) to the total energy supplied was only 60.2 per cent. from the half-watt lamp as compared with 83.4 per cent. from an ordinary Osram lamp, the lower figure being due to the loss by convection in the gas. On the other hand, owing to the higher temperature of the filament in the half-watt lamp, the visible radiant energy was 8.04 per cent. of the total radiant energy as compared with a percentage of 3.76 in the case of the ordinary metal filament. As a final result, the percentage of light energy to the total energy input or the absolute light efficiency is 4.82 per cent. for the half-watt lamp as compared with 3.32 per cent. for the ordinary lamp. [The corresponding "efficiencies" or specific consumptions were 0.56 and 1.47 watts per Hefner spherical candle-power.] It is interesting to note that the 1000 c.p. half-watt lamp, absorbing 525 watts, gave out over 25 watts in light energy.

The experiments were made with highly accurate apparatus and compare very well with previous determinations by other authorities. Thus W. Coblentz, of the Washington Bureau of Standards, found the percentage of light energy to total radiant energy from the half-watt lamp to be 7.6 per cent., as compared with Dr. Lux's 8.04 per cent.

Dr. Lux points out the fact that for the same temperature of filament, for example,  $2400^{\circ}$  absolute, the ordinary metal filament has an efficiency nearly 19 per cent. higher than the "half-watt" filament in nitrogen, the figures being 0.76 spherical candle per watt and 0.64 spherical candle per watt respectively. This is partly due to the loss of energy by convection in the nitrogen-filled globe of the half-watt lamp. According to Langmuir's experiments, this loss by convection is reduced to about one per cent. only when the filament is

wound in a spiral of about 2 mm. diameter, and Dr. Lux asserts that the remaining loss of 17 per cent. or more is due to the wasted light given off into the interior of the closely-wound spiral. This wasted light is, of course, converted into heat, and helps to account for the low percentage of energy converted into radiant energy (60 per cent. as compared with 88 per cent. for the Osram lamp) in the case of the half-watt lamp tests described above.

## THE FIRE AT SPIERS AND POND'S

THE fire in the early hours of Wednesday morning of last week at Spiers and Pond's premises in Water Lane, off Queen Victoria Street, entailed damage by water to the firm's private generating plant which supplies not only the whole of Spiers and Pond's stores and adjoining departments, but also the Holborn Viaduct Hotel and one or two other private customers. Although the fire originated in the lower part of the building, travelling up the lift shaft and burning out the upper floors, the stoppage of the generating station was not due to fire, but to it being flooded with water pouring down the lift shaft. The station, which was established about twenty-five years ago, and has scarcely been altered since, contains six 52-kw. bipolar Mather & Platt continuous-current generators driven by Willans engines supplied from Babcock & Wilcox boilers with underfeed stokers. The water in the boiler-house reached right up to the grates, but in the engine-room, which is on a slightly higher level, did not quite reach the armatures. The cables from the machines to the switchboard were, however, submerged. It reflects great credit on the staff that the water was pumped and baled out, and the boilers under steam again by 5.30 in the afternoon, and that after a certain amount of drying out the generators were put on to a limited amount of load by 9.30, while the work of renewing the cables to the switchboard was at once put in hand.

In the meantime, however, efforts were made to obtain a temporary supply for the Holborn Viaduct Hotel, and after negotiations with the supply authorities in the district, instructions were given about midday to the City of London Electric Lighting Supply Co. to proceed with arrangements for connecting up the hotel to their A.C. mains, and by 3.30 all was planned out and work was started. Cable was run from the other side of Holborn through a subway, but 4 ft. of concrete had to be cut through to effect an entry into the basement. The cable was then led up the building to the main switchboard at the back of the first floor by a route involving a total run of cable of about 300 ft. An extremely smart piece of work was accomplished, and the supply to the hotel was started by 7 o'clock that evening. As the supply was alternating, a few fans and other small motors had to be disconnected.

In the case of Spiers and Pond's own premises, one of the most serious matters was the stoppage of the refrigerating plant, which is driven by two 40-h.p. 110-volt continuous-current motors. The City of London Co. promptly offered to replace these by A.C. motors, and have the plant running again the same day, which would have been a very smart piece of work considering the difficulty of access to the small underground chamber in which their plant is placed, but this course was not considered necessary, and the motors were started up again at 6 o'clock on Thursday morning.

Great credit is due both to Messrs. Spiers and Pond's own electrical staff and to the City of London Co. for the prompt way supply was got going again, and mention should also be made of the assistance rendered by the Salvage Corps in protecting the machinery from damage as far as possible. We wish to express our thanks to Mr. F. Kieffer, Chief Assistant to Messrs. Spiers and Pond's Engineer, who showed our representative over the plant after the fire.

**Electrical Exports for Canada.**—We have received from the B.E.A.M.A. a copy of a letter to them from Mr. Dana Pierce, Engineer to the Underwriters' Laboratories, National Electrical Code, Chicago, regarding the arrangements for inspecting electrical apparatus destined for Canada, which has to conform with the United States Electrical Code. Mr. Pierce points out that Messrs. Heap & Digby (48 Westminster Palace Gardens, Victoria Street) represent the Underwriters' Laboratories in England and undertake examinations of all such apparatus. The American Code naturally represents practice differing in some respects from that prevailing here, and British manufacturers must expect to have to adapt their wares to some extent to the special requirements existing in Canada. It is, of course, impracticable to discuss all these differences of practice in a general review of the code, but it is always open to manufacturers to raise any points of detail which it is desired to consider.

## PRE-HEATER AT POPLAR ELECTRICITY WORKS

IN view of the controversy as to the advisability of heating the air which is supplied to boiler furnaces, we give below some particulars of the air-heater which has been in use at the Poplar Electricity Works for some time. The general arrangement of the system can be seen from the drawing below. Air is drawn from the heated interior of the boiler-house by the fan A, and is forced through the heater B and down the delivery pipe, which passes underneath the boiler. From here two branches are taken, one to each grate, so that the heated air enters through the fire bars, passes up through the burning fuel, and thence through the heater, where it serves, in its turn, to heat the incoming air, and from here up the chimney. The boiler is a Babcock & Wilcox marine type, with heating surface of 6,295 sq. ft. fitted with "Underfeed" stoker having a grate area of 154 sq. ft. The air-heater, which was supplied by the Underfeed Stoker Co., has a heating surface of 3,132 sq. ft. The superheater, which is by Babcock & Wilcox, has heating surface of 1,131 sq. ft. The following figures are from a test which was made on the boiler immediately after the air-heater had been installed.

ARRANGEMENT OF AIR HEATER.

Since then some improvements have been effected, so that the results obtained at present are somewhat better than are here shown:—

Duration of test	9 hrs.
Temperature of air entering heater	105° F.
Temperature of air leaving heater	214° F.
Temperature of gases leaving boiler	579° F.
Temperature of gases leaving heater	401° F.
Power taken by fan	19 kw.

Equivalent evaporation from and at 212° F. = 6.19 lb. per hr. per sq. ft. of heating surface.

In passing through the heater the air is caused to flow through a number of narrow channels, the outsides of which are scrubbed by the hot flue gases. Each day all deposited soot is removed from the inside of the heater by steam sprays, which are fed with live steam by 1½-in. diam. pipes, the time occupied being about ten minutes. Apart from this the attention required by this heater is practically nil. Although the results obtained from this heater are not quite so good as are obtained from an economiser which is fitted to a similar type of boiler in the same station, there is no reason to doubt that in many cases the system of pre-heating may be adopted with advantage. We are indebted to Mr. J. H. Bowden, Borough Electrical Engineer, Poplar, for the details given above, and for permitting us to inspect the pre-heater at the Poplar works.

## A HOSPITAL INSTALLATION

THE extent to which electricity is employed in a modern hospital is strikingly exemplified in the equipment of The Royal Hospital for Sick Children, Yorkhill, Glasgow, which was opened by the King and Queen recently. Artificial illumination is provided for by nearly 2,000 electric lamps. Thirteen lifts and the whole of the laundry, kitchen, and other machinery are worked by electric motors, of which there are in all upwards of forty. The ventilation is entirely

by electrically-driven fans. There is an extensive inter-communication telephone system having thirty stations, in addition to the Post Office instruments, of which there are five. The clocks throughout are electrically operated and controlled as also are the several bell systems. In addition to these ordinary utilitarian services there is the very extensive and varied use of electricity in electro-surgery, Röntgen ray, high frequency, and other special apparatus too numerous to mention in detail.

The electrical supply is from the Glasgow Corporation mains, and is brought in duplicate cables to each of two main switchboards in the basement. The arrangement constitutes a very reliable safeguard against interruption of supply. The operating theatres are provided with similar duplication with the same object. The equipment has been installed almost entirely by the following firms: Telford, Grier & Mackay, Ltd., carried through the lighting and general electrical installation work; R. Waygood, Ltd., the lifts; and D. & J. Tullis, Ltd., the laundry machinery. Royal Edisonwan drawn-wire metal filament lamps are used throughout. The electric clock and telephone systems are by the Magneta Time Co. and the Sterling Telephone Co respectively. Expert service on behalf of the Hospital Board has been rendered by Messrs. James E. Sayers & Caldwell, Consulting Engineers, of Glasgow.

## EDISON BATTERY OMNIBUSES

CONSIDERABLE interest attaches to the two electric omnibuses which have just been supplied by Edison Accumulators, Ltd. (203 Duke Street, Piccadilly, S.W.), for public service in South Shields. These vehicles are to be used by the Corporation as feeders to the tramway system, and are to run over a route about 1½ miles in length, which includes two gradients, one a sharp dip down to a level crossing, and the other a bridge over a railway.

The vehicles, one of which is illustrated here, are of the single-deck pattern to seat twenty-two passengers, and weigh about 8½ tons unloaded. The battery is contained in sheet-steel housings in two longitudinal sections in the body under the seats, and consists of sixty cells of the Edison A-8 type, with a capacity of 300 ampere-hours at 65 volts. The battery weight is 1,800 lb. One motor is employed, and this is mounted under the driver's footboard, and the transmission is

EDISON BATTERY OMNIBUS FOR SOUTH SHIELDS.

by a propeller shaft to a differential bevel countershaft and side chains. The motor is of the four-pole series, totally-enclosed type, with cast-steel case and laminated pole-pieces, oil-retaining ball-bearings, and specially large commutator. The drum-type controller is placed under the front hood. It is actuated by a lever to the left of the steering column, and provides for four forward speeds and two reverse. The brake pedals are interlocked with a cut-off switch. An ampere-hour rocker is mounted flush into the dashboard. The vehicle is designed for a speed of 12 miles per hour on the level, and during recent trials in London, Aubrey Road, Holland Park, where the maximum rise is 1 in 8 and the average 1 in 10, was climbed at about 6 miles per hour. From 40 to 50 miles can be obtained per full charge on good roads, and with short boosting at the termini between each trip, 80 to 100 miles per working day. The body is of a special design, with front entrance, and the lighting is furnished by an independent Edison battery of six A-4 cells arranged to be charged with the traction battery at night. We understand that a similar vehicle is being put into service at Southend.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,401.

As a charge-engineer of a generating station, what would you consider the minimum temperature of the coils of a generator or transformer at which you should report that something was wrong? (A) In the case of cotton insulation. (B) In the case of mica or micanite insulation.

(Replies must be received not later than first post, Thursday, July 30th.)

### ANSWER TO No. 1,399.

A Hartmann & Braun hot wire voltmeter is used on A.C., and has a scale of 0-250 volts. It is desired to use this instrument for a range of 0-500 volts by multiplying present scale by two. How can this be accomplished?—METER.

The first award (10s.) is given to "INSTRUMENTS" for the following reply:—

Since the Hartmann and Braun hot wire voltmeter is for all practical purposes non-inductive, it will be safe to add in series a non-inductive extra resistance of the same value as that of the present voltmeter. The instruments of 250-volt range have usually a negligible temperature error, but it will be a wise precaution to measure the voltmeter resistance hot—heated by the usually measured voltage being applied for about twenty minutes. A suitable form of non-inductive resistance can be constructed by winding single silk-covered manganin or eureka wire on such a frame (or frames) as is shown in sketch. The size of wire to be used depends on the current taken by the instrument at its maximum deflection—usually of the order of 0.1 to 0.15 amperes. As a guide it

may be pointed out that 0.006 manganin or eureka wound open (i.e., the turns not touching) on the suggested frame will carry safely 0.06 ampere, while 0.008 wire will carry about 0.1 ampere. The resistance may be adjusted on the bridge, and finally checked by measuring its resistance immediately after a twenty minutes' application of about 250 volts. If a Wheatstone bridge is not available, the extra resistance may be adjusted till it halves the voltmeter reading when put in series with it, a constant voltage being employed.

Thus if the instrument alone reads 240 on the application of this voltage, the extra resistance should reduce this reading to 120 when put in series. Sometimes the Hartmann and Braun voltmeters are supplied with small figures over the scale beside the voltage figures. These give the current taken by the voltmeter at the several deflections. If this is the case with "Meter's" voltmeter the settling of the size of wire to use is simplified, as no resistance measurement of the instrument will be required. The makers will usually give the current taken if the instrument number is given.

The second award (5s.) is given to "W. H.," who writes as follows:—

It will be found that a considerable amount of power is wasted when using a Hartmann and Braun hot wire voltmeter on a 500-volt circuit. The current taken by these instruments is usually in the neighbourhood of 0.25 amperes, and the "wire" itself has a resistance of approximately 20 ohms. This means that the total resistance of the voltmeter will be about 1,000 ohms. It will be best to measure the actual voltmeter resistance on the Wheatstone bridge, and then to wind bobbins with resistance wire up to exactly the same number of ohms as the total voltmeter resistance. In order to use the voltmeter on 500 it will be necessary to connect the resistance box in series with the voltmeter itself.

The scale reading will then, of course, be multiplied by two to give the actual voltage of the circuit. It would be as well to have a voltmeter switch to save the power that would otherwise be wasted when the voltmeter reading is not actually required. I would suggest winding the resistance of, say, Eureka wire on small bobbins, the bobbins to be fixed in a ventilated wooden box provided with the necessary terminals. If a switch is used it will probably be satisfactory to use about S.W.G. 30 Eureka wire, and as, approximately, 1,000 ohms will be required, this will mean about 179.4 yds. of double cotton-covered wire, or 1/4 lb. bare weight of wire. Allowing for insulation, this will be about 3 lb.

This wire could be wound on about six wooden bobbins, each about 2 1/2 in. long by 1/2 in. diameter, and allowing 1/2 in. depth of winding. As it is for use on an A.C. circuit, it will be advisable to wind the wire non-inductively. This can be done by winding two wires simultaneously, after first soldering the ends together. These six bobbins could be mounted in a small wooden box about 6 in. by 4 1/2 in. by 1 1/2 in. provided with plenty of holes for ventilation purposes.

The "hot" wire of a Hartmann & Braun voltmeter is made of platinum iridium, which has a lower temperature coefficient than the platinum silver formerly used. Its resistance, however, is so small a part of that of the whole instrument that it is unnecessary to allow for its temperature coefficient in the series resistance (as has been suggested in some replies received) or, except as a general precaution, to recalibrate the instrument. —[Ed. E.E.]

**An Electric Emergency Vehicle.**—The West Ham Corporation has ordered an interesting vehicle for emergency work on their tramway and supply system. This will consist of a one-ton lorry chassis supplied by Edison Accumulators, Ltd., fitted with the usual type of tower and platform for working on tramway overhead lines and poles. The whole of the tower and superstructure, however, will be arranged so that it can be removed from the chassis in a few minutes, and a plain float can be affixed in place of it, so that the vehicle becomes available for mains emergency work, and general transport service. The equipment will also include substantial watertight lanterns and flexibles for night work, a portable electric drill, and a small electrically-driven centrifugal pumping outfit for emptying flooded substations and similar work.

**Electrolytic Disinfecting Fluid.**—It is now eight years since the manufacture of electrolytic hypochlorite disinfectant was taken up by the Borough of Poplar, and the annual report for 1913 records an output of 66,740 gallons during the year at a total cost of £135. The success of the process used, in which the hypochlorite of magnesia solution is prepared by the electrolysis of Water Board water, containing certain definite proportions of sodium chloride and magnesium chloride, is shown by the fact that in addition to the plants already supplied to the British War Office and Admiralty, quite recently plants have been sent to Finland, Buenos Aires, and Rangoon. The Gateshead Municipal Corporation have also given an order for a plant to be erected, and while this report is being written, a large plant is being installed for the Portsmouth Corporation. It is interesting to note that in the last case the fluid to be electrolysed is sea-water itself, which, of course, is close at hand, and a ready and powerful disinfectant is manufactured by this process without cost of materials, but merely that of electric current. Various improvements have been made in the plant since it was first installed, and a non-creeping slate cell is now replacing the original earthenware cells.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published July 16th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

**Names in italics indicate communicators of inventions from abroad.**

**14,140/13. Wireless Transmitter.** W. P. THOMPSON (*Cie Universelle de Telegraphie et de Telephonie sans Fil*). An arrangement by which a high-frequency, heavy current generator can be made to supply current efficiently, and at double the original frequency, to the antenna. Two or more similar transformers are used. Each transformer has a closed magnetic circuit and primary, secondary and auxiliary windings. All the primaries are connected in series, and are excited by the generator; the secondaries are also connected in series, and supply current to the antenna. The auxiliary windings are wound on the transformers so as to produce a flux at right angles to the main flux in each case. They are connected in series, and are excited from a source of direct current. It is found that the above arrangement obviates the heavy losses which have hitherto been encountered when "tight coupling" of the transformer circuits has been used. Also the secondary frequency is found to be twice that of the generator. Two figures.

**16,066/13. Tungsten Filaments.** E. A. KRÜGER. Powdered tungsten is mixed with about 1.0 per cent. of boracic acid and 0.1 per cent. of carbon, and compressed into a rod. The latter is then heated to 1000-1200° C., the temperature being maintained for some time. An electric current is then applied, and the temperature is raised to 1200-2000° C., during which process a stream of hydrogen is passed through the heating chamber. The rod may then be hammered, rolled, and drawn into wire.

**5,478/14. Decrement Meter.** F. A. KOLSTER. An instrument for measuring the logarithmic decrement of circuits such as are employed for wireless signalling. It consists of a hot-wire ammeter in series with an inductance and a variable condenser. The plates of the latter are so shaped that the capacities of the condenser for different positions of its plates vary according to the law of geometrical progression. In use, the instrument is inductively coupled to the circuit of which the decrement is to be measured, and the capacity is adjusted to give a maximum deflection on the ammeter. The capacity is then decreased until the ammeter reading is reduced to half its maximum value. The spindle for rotating the condenser plates is now mechanically connected through gearing to a graduated dial, and the capacity is increased by rotating the spindle until the ammeter reading rises to the maximum and then falls to the half maximum value again. The movement of the spindle is registered by the rotating dial. The reading obtained is the sum of the decrements of the circuit under test and of the instrument circuit. By subtracting the latter, the required decrement is obtained, without the necessity for elaborate calculations. Six figures.

**8,595/14. Welding Machine.** A.E.G. A continuous strip of thin metal is passed through rollers, which bend it into tubular form with edges slightly overlapping. This tube then passes over a smooth mandrel, the end of which is large enough to completely fill the bore of the tube. The welding roller presses upon the lap seam and is connected to one pole of the generator. A larger conducting roller engages the side of the tube opposite the welding roller. Most of the current passes through the mandrel in flowing from the point of welding to the conducting roller. Hence very thin tubes can be successfully lap-welded by this process. Three figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Electrodes] 18,355/13.

**Distributing Systems, Cables and Wires, &c:** MELLERSH-JACKSON (*U.S. Light & Heating Co.*) [Dynamo regulating systems] 12,578/13; HARRIS [Relay systems] 15,251/13; STORER [Motor control] 22,390/13.

**Dynamos, Motors and Transformers:** LJUNGSTROM [Dynamo windings] 4,979/14; SIEMENS SCHUCKERTWERKE GES. [Induction regulators] 10,493/14; R. BOSCH [Brush-holders] 10,945/14.

**Electrometallurgy and Electrochemistry:** RENNERFELT [Furnaces] 226/14.

**Ignition:** KETTERING and CHRYST [Ignition systems] 7,465/14.

**Incandescent Lamps:** SCOLAR and DICK, KERR & Co. [Metallic

filaments] 14,807/13; WESTINGHOUSE METALLFADEN GLUHLAMPEN-FABRIK GES. [Lamps] 540/14; BIRKETT and WEISS [Lamps] 6,050/14.

**Storage Batteries:** SCOTT [Regulators for accumulator charging] 14,741/13; FOSS, HARRIS and PARKER [Alkaline accumulators] 16,027; PORDES [Battery casing] 5,506/14.

**Switchgear, Fuses, and Fittings:** VON VANGEL [Automatic contact apparatus] 12,428/13; COX [Fuses] 17,174/13; ROGERS and DAVIES [Safety device for motors] 24,226/13.

**Telephony and Telegraphy:** BALSILLIE [Wireless transmitter] 15,673/13; DERRIMAN (*Russell*) [Telephone systems] 15,748/13; SHAW [Telephone systems] 5,246/14.

**Traction:** STEVENS [Petrol-electric vehicles] 15,516.

**Miscellaneous:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Vacuum tubes] 14,892/13; ACCUMULATOR FABRIK AKT. GES. & RÜSSE [Fire-damp detector] 15,064/13; EDWARDS [Signalling apparatus for collieries] 4,436/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, Cables, Wires, &c:** SOC. D'ELECTRICITÉ DE PARIS [Relays] 13,335/14; SIEMENS SCHUCKERTWERKE GES. [Tensioning overhead conductors] 14,683/14.

**Dynamos, Motors and Transformers:** SIEMENS SCHUCKERTWERKE GES. [Polyphase commutator machines] 13,136/14; A. E. G. [Mercury rectifiers] 15,076/14.

**Electrometallurgy and Electrochemistry:** SOC. ANON. L'OXY-HYDRIQUE FRANÇAISE [Electrode carriers] 13,589/14; MACHALSKE [Electric furnaces] 15,455/14; [Electrodes] 15,456/14; [Ore smelting] 15,457/14.

**Ignition:** SOC. D'ELECTRICITÉ NIMELIOR [Oiling of magnetos] 15,352/14; BETHENOD [Magnetos] 15,353/14.

**Telephony and Telegraphy:** BURFEIND [Telephone systems] 14,808/14; DARRAS [Condensers] 14,834/14; GIRARDEAU [Spark-gaps for wireless] 14,884/14.

**Traction:** CIE. DE SIGNAUX ELECTRIQUES POUR CHEMIN DE FER [Railway signalling] 13,961/14.

**Miscellaneous:** SIEMENS SCHUCKERTWERKE GES. [Searchlights] 13,920/14.

The following Amended Specifications may now be obtained:—

**Switchgear, Fuses, and Fittings:** J. BLIJR [Circuit breakers] 9,426/12.

**Incandescent Lamps:** WESTINGHOUSE METALLFADEN GLUHLAMPEN-FABRIK [Manufacture of tungsten] 3,162/13.

**Telephony and Telegraphy:** SIEMENS & HALSKE AKT. GES. [Semi-automatic telephony] 6,936/13.

### Opposition to Grant of Patents

1,915/13. **Manufacture of Tungsten.** B.T.-H. Co. The grant of this patent has been allowed by the Comptroller.

### Amendments

12,082/13. **Arc Lamps.** H. AYRTON. Application has been made for leave to correct this specification.

25,591/13. **Duplex Telegraphy.** EASTERN TELEGRAPH CO. and RYAN. The above specification has been corrected.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** M. WITTGENSTEINER [Feed mechanism] 7,508/09.

**Distributing Systems, Cables and Wires, Insulating Materials, &c:** A. H. JACKSON [Motor control] 7,335/08; A. G. BROOKES (*Thomas & Betts Co.*) [Cable coupling] 7,576/09; W. SCHMAHL and AMORDUCT MFG. CO. [Armouring] 7,706/09; R. K. GRAY [Submarine cables] 7,791/09.

**Dynamos, Motors and Transformers:** M. MILCH [Field regulation] 7,919/06; B.T.-H. Co. and F. H. CLOUGH [Dynamo windings] 7,327/08.

**Electrochemistry and Electrometallurgy:** A. G. BEITS [Lead refining with fluoric electrolyte] 7,661/02.

**Ignition:** A. ZÄBRINGER [Distributing switch for magnetos] 7,014/08.

**Telephony and Telegraphy:** J. SCHLISSLER [High-frequency oscillator] 7,028/08; [Wireless telephony] 4,026/09; [Magnetically-controlled condenser] 4,028/09; W. BURSTYN [Wireless telephony] 7,906/09.

**Traction:** H. PIEPER [Petrol-electric vehicles] 7,526/04.

**Miscellaneous:** J. GARDNER [Controlling apparatus by sound] 7,654/06; A. J. BOULT (*O. Patin*) [Water purifier] 6,949/08; W. E. LAKE (*Electrelle Co.*) [Musical instruments] 7,233/08; P. G. SHILSTON [Signalling lamp] 7,300/08.

## ELECTRIC TRACTION NOTES

In one of the Papers read before the Congress of the Tramways and Light Railways Association at Newcastle, Mr. H. M. Sayers detailed some experiences in tramway construction in Brazil, and gave some interesting particulars of the special circumstances and difficulties which arose during the reconstruction of the tramways at Santos. The problem was complicated by the necessity for keeping the old mule routes at work during the reconstruction and alterations in the requirements of the local authorities. On certain parts of the routes, cross-wood sleepers were employed, with Vignoles rails on the beach and other lines and grooved rails in the paved streets. Concrete stringer construction was used in the older and central streets, as no alternative method was agreed to. There was, however, some trouble with transverse fracture of stringers, which Mr. Sayers considers unavoidable where anchor plates are used at rail joints, and there are violent changes in the temperature. Rail expansion gave a good deal of movement of the track on the unpaved roads, and on short radius curves the lateral shifting was as much as four inches between night and day. There was no difficulty in running the same cars on the Vignoles and grooved rails. The tramway poles also carried telephone and other wires, and a good deal of trouble was experienced with storms causing the telephone wires to fall across the others. A considerable amount of goods traffic is handled with motor and trailer waggons of 4 and 6 tons capacity.

Another Paper, by Mr. F. Bland, on "Standard Tramway Rails," contained a comparison between English and foreign sections. The difference in  $\frac{1}{4}$  in. in the depth of the groove between the Continental and English standard rails was noticed, although the running treads were practically the same. America has now standardised four sections, after six years' consideration, but these have not yet been put into practice. Mr. R. Humphries also read a Paper on rail joints. He described various forms of joint, and classified them as follows:—Fish-plated joints, with or without base supports; welded joints without fish-plates; and welded joints with fish-plates. He had no hesitation in advocating the last, and described the electric welding equipment used on the Birmingham and Midland Tramways. A motor-generator is carried on a special car, and arc welding is used for filling in dished joints and welding the fishplates to the rail. The conductivity of the joint is improved, and bonds can be abolished. Descriptions were also given in the Paper of the well-known Thermit and cast-welding methods. It was stated that great care and skill were necessary with both of these, while an objection to the latter was the elaborate equipment required. In another joint a shoe is welded by the oxy-acetylene process to the base of the rail. The Tudor Accumulator Co. have developed a method of "quasi-arc" welding, in which they use an electrode of Swedish iron coated with slag. In addition to welding fish-plates they have a machine for welding a strip of metal on the tread of the rails. The Lorain Steel Co. have an electric butt welding system of rail jointing, but this requires a plant occupying no less than five cars. Welding currents at as much as 25,000 amperes at 5 volts are used.

In calling attention at the last meeting of the Corporation to the large deficit of £14,421 upon the West Ham Corporation Tramways last year (referred to in our last issue), the Chairman of the Tramways Committee mentioned that the cost of track maintenance was no less than £22,035, as against £14,061 and £8,799 in the two preceding years. This expenditure was largely brought about by exceptional vehicular traffic, and the unrestricted use of the tramway tracks needed, he said, the earnest and serious attention of the Council. It is proposed to call upon the rates for £10,000 of the deficit and charge the remainder to reserve. In doing so, it should be pointed out that the undertaking has already contributed £35,740 from profits in relief of rates, in addition to some £33,081 by way of rates under the ordinary assessment.

Under the Standing Orders of the L.C.C., schemes for new tramways must be presented before the summer recess. The Highways Committee are asking for the suspension of these Standing Orders, to bring up in the autumn a scheme for abolishing a number of dead ends and generally linking-up, at a cost of about £1,000,000. Already the views of M. Mariage, the Paris tramway and omnibus expert, have been obtained, and it is in order to consider these more fully that the suspension of the Standing Order is sought.

The Bill of the London Brighton & South Coast Railway Co., which was before a House of Commons Committee last week, dealt, among other things, with the provision of electrical energy for dealing with the Co.'s projected 200 miles of new electric railways. Power was taken under the Bill to enter into agreements with the County of London Electric Supply Corporation, but the London County Council opposed, on the ground that these agreements would carry beyond 1931, the date when the L.C.C. may purchase the London supply companies. Eventually it was decided that any agreements entered into between the Railway Co. and the Supply Co. should be submitted to the L.C.C. for consent, so far as they relate to the period subsequent to 1931. Opposition was also offered to the Bill by the Croydon Corporation, and in this case the Committee's decision was that any current supplied by the London Electric Supply Corporation to the Railway Co. should only be used in Croydon for purely railway purposes, and not to any premises which the Company might own and let.

In answer to a question in the House of Commons last week, it was stated on behalf of the Postmaster-General that tenders will shortly be invited for the construction of the tunnel for the new Post Office underground electric railway. An experimental track has been constructed on War Office property with a view to carrying out certain tests.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The following Committee has been appointed to consider the organisation of the telegraph service, and to report as to the improvement of its efficiency and economy:—Sir Archibald Williamson, Bt., M.P. (Chairman); Sir Henry Norman, M.P.; Sir Charles Stewart-Wilson, K.C.I.E.; Sir William Plender; and Mr. A. M. Ogilvie, C.B.

With regard to the recent Press notices concerning a contract between Marconi's Wireless Telegraph Works and the Chinese Government, it is officially stated that negotiations have been pending between the parties for some time for the erection of a number of wireless stations in China for internal and external services. The Company has every confidence that in due course an agreement will be signed.

A circular has been issued by six Irish shareholders of Marconi's Wireless Telegraph Co. criticising the report for the past year, given in our last issue. Complaint is made that the report does not show what profit, if any, is made by the sending of messages, and the contract for the Imperial wireless scheme is regarded as not having proved a success. A number of other details are dealt with in the circular, and shareholders are invited to communicate with Mr. E. F. Sheils, Dame House, Dame Street, Dublin.

At the annual meeting of Marconi's Wireless Telegraph Co. on Tuesday, Mr. Marconi, the Chairman, and Mr. Godfrey Isaacs, the Managing Director, although not on the list to retire, did so, "in view of the extraordinarily false rumours which are constantly circulated, and of the poisoned atmosphere by which," said Mr. Isaacs, "I have been recently surrounded." In the subsequent voting the Chairman was unanimously re-elected, and Mr. Isaacs was also re-elected with but one or two dissentients. The report and balance-sheet were adopted; an amendment to adjourn the consideration of them until a proper and detailed balance-sheet, and trading, and profit and loss account were submitted to the shareholders was not seconded. The general tone of the meeting was to deprecate any attack upon the Board in view of the work which has been accomplished.

In answer to a question in the House of Commons on Tuesday it was stated that no application has been made by Marconi's Wireless Telegraph Co. for a renewal of Patent 7,777, which expired, after the normal life of fourteen years, on April 26th. Questions were also asked as to whether the Government could claim compensation with regard to this expiry under the Imperial wireless telegraph scheme, but the reply was that all such matters were dealt with under the agreement.

The cable between St. Jacques and Doson failed on the 17th inst., and telegrams are being sent by land-line, subject to delay.—The land-line between Behbahan and Ahvaz was down beyond the former place on the 20th inst.—The Scutari, Lesh, s'Giovanni di Medua, and Vallona offices only are transacting international business, and telegrams for Durazzo can only be accepted at senders' risk.—Telegrams for other places in Albania cannot be sent at the moment.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 425. —

### HALF-WATT LAMPS: NEW SIZES AND PRICES

ON Monday five new sizes of "half-watt" lamps were put on the market in this country, and prices were also considerably reduced. The new sizes are:—200 to 255 volts, 500 watts; 100 to 130 volts, 200 and 300 watts; and 50 to 65 volts, 100 and 200 watts.

25 volts, 50-watt 100 c.p. and 100-watt 200 c.p. are also in use in Germany, and may possibly find their way to England for those cases in which 25 volts was adopted when the metal filament lamp was first introduced. In Germany, also, as mentioned in our columns recently, 14-volt lamps of 50, 100, and 200 c.p. (25, 50, and 100 watts) are also on the market for use with small lamp-holder transformers on A.C. systems. For

FIG. 1.—OSRAM 210-VOLT 500-WATT LAMP.

FIG. 2.—FILAMENT OF 200 V. 500 W. OSRAM LAMP, ABOUT 2/3 SCALE.

FIG. 3.—FILAMENT OF 100 V. 1,000 W. OSRAM LAMP, ABOUT 2/3 SCALE.

FIGS. 4 AND 5.—FILAMENT AND ATTACHMENT OF OSRAM "VERTICAL" AND "HORIZONTAL" PROJECTOR LAMPS. FULL SIZE.

FIG. 6.—OSRAM 100-VOLT 1,000-WATT "VERTICAL" PROJECTOR LAMP. ABOUT 1/2 SIZE.

The whole range of half-watt lamps now obtainable is as follows:—

Voltage.	Watts.	Old List Price.	New List Price.
200 to 255	500	—	30s.
200 to 255	1000	50s.	40s.
"	1500	60s.	50s.
100 to 130	200	—	20s.
"	300	—	25s.
200 to 255	500	35s.	30s.
"	1000	50s.	40s.
"	1500	60s.	50s.
50 to 65	100	—	15s.
"	200	—	20s.
50 to 65	300	30s.	25s.
"	500	35s.	30s.

The new sizes are printed in heavier type. In all cases the candle-powers (Hefner) are twice the wattages.

The lamps rated at 300 watts and over are supplied with "Goliath" caps, and the smaller sizes with standard Edison screw caps.

It is probable that lamps of 300 watts (600 c.p.) for voltages between 200 and 230 will also be obtainable shortly (although these are not yet officially announced), as this size is on the market abroad, and the same remark applies to 150-watt lamps at 100 to 130 volts. On installations with transformers reducing to

FIG. 7.—OSRAM HALF-WATT LANTERN FOR SERIES CIRCUITS.

motor-car head-lamps, half-watt lamps of 50 and 100 c.p. are also on the German market, the former in 6 and 8 volt sizes and the latter for 6, 8, 10, or 12 volts.

Another welcome step in the progress of the half-watt lamp is the introduction of special half-watt lamps for projection purposes. These are made with the filament spirals very close together. Focusing lamps of this type are listed at present only in voltages between 100 and 130 and for 300, 500, 1,000, and 1,500

watts. The 1,500-watt (3,000 c.p.) size is suitable for small cinematographs with a picture 10 ft. in diameter, and the other sizes will be found useful for magic lanterns, photographic enlarging, &c. These lamps are obtainable both with filaments parallel to and at right angles to the axis of the lamp.

We have received detailed particulars from a number of firms:—

#### Osram Half-watt Lamps.

The new 200 to 255-volt 500-watt lamp is illustrated in Fig. 1, which is a little less than half actual size; the diameter

and hood for series running (in place of arc lamps) with self-contained automatic cut-out and substitutional resistance. This is made in 300, 500, and 1,000-watt sizes; a distribution curve for the 1,000-watt size sent us shows a maximum candle-power of about 2,500 vertically below the lantern, increasing gradually to the maximum of about 3,100 at 60 deg., and then falling back to about 2,500 at 75 deg.—a most useful shape of illumination curve for lighting streets and open spaces. The General Electric Co. inform us that experience with the  $\frac{1}{2}$ -watt lamps which have been on the market since January is that the stated average life of 1,000 hours has been well maintained, and they have sent us copies of testimonials from users which bear this out.

FIG. 8.—MAZDA 200 v. 1,000 w. LAMP. ABOUT  $\frac{1}{2}$  SIZE.

FIG. 9.—MAZDA 100 v. 500 w. PROJECTOR LAMP.

FIG. 10.—MAZDA 50 v. 100 w. LAMP. ABOUT  $\frac{1}{2}$  SIZE.

FIG. 11.—WOTAN 50-65 v. 100-WATT LAMP. ABOUT  $\frac{1}{2}$  SIZE.

FIG. 12.—WOTAN 100-130 v. 200-WATT LAMP. ABOUT  $\frac{1}{2}$  SIZE.

FIG. 13.—WOTAN 1,000-WATT PROJECTOR LAMP. ABOUT  $\frac{1}{2}$  SIZE.

of the bulb is 6 ins. Fig. 2 shows the filament on a larger scale. Fig. 6 is a 100-volt 1,000-watt projector lamp of the "vertical" type; Figs. 4 and 5 depict the filaments of these projector lamps and their method of attachment to larger scale, showing how the filament spirals are arranged close together on one plane in both the "horizontal" and "vertical" types, and Fig. 3, drawn from an ordinary  $\frac{1}{2}$ -watt 100-volt 1,000-watt lamp, enables a comparison to be made. The bulbs of the projector lamps are considerably smaller than those of the ordinary  $\frac{1}{2}$ -watt lamps of the same wattage. Another interesting illustration is Fig. 7, which is a  $\frac{1}{2}$ -watt lamp arranged in a lantern

#### Mazda Half-watt Lamps.

The list of Mazda half-watt lamps, including the new sizes and prices, which has just been issued by the British Thomson-Houston Co., has on its cover a fine reproduction of an untouched photograph showing the Leeds City Square lighted by Mazda half-watt lamps, and the company informs us that their half-watt lamps are everywhere replacing other forms of high candle-power units. They have sent us the three illustrations above of the new sizes. Fig. 8 is a 1,000-watt 200-volt lamp, about  $\frac{1}{2}$  size; Fig. 9 shows their form of projector lamp (which may also be had with horizontal filament), and Fig. 10 a 50-volt

100-watt lamp. It will be noticed that the 100 and 200-watt lamps, compared with the ordinary tungsten lamps of the same wattage and half the candle-power, are actually of smaller dimensions, and will therefore find much favour for interior lighting in cases where the voltages are suitable. We are asked to state that full information with regard to Mazda half-watt lamps and fittings may be obtained at the company's lamp and supplies department at 77 Upper Thames Street, London, E.C.

### Wotan Half-watt Lamps.

Three of the Wotan half-watt lamps are illustrated on p. 423, and the makers, Siemens Bros. Dynamo Works, Ltd. (Tyssen Street, Dalston), call our attention particularly to the small sizes of the bulbs. Fig. 12 shows the 100 to 130-volt 200-watt lamp, which is only 4 ins. in diameter. The 50 to 65-volt 100-watt lamp (Fig. 11) is of the same diameter, but only 6½ ins. long. Fig. 13 shows the Wotan projector lamp, with vertical filament; a similar lamp is made with horizontal filament. The makers expect a good demand for the former for outside shop lighting, and the horizontal type for theatre auditoriums and similar positions in which the light is placed high above the floor.

### Nitra Half-watt Lamps.

The Nitra half-watt lamp, sold in this country by the A.E.G. Electric Co., Ltd. (Pembroke House, Oxford Street), and the Electrical Co., Ltd. (122 Charing Cross Road, W.C.), is manufactured by the German A.E.G. Co., and is the outcome of extended experimental work in the company's laboratories. The sizes are the same as those mentioned in the first part of this article on p. 422, and the firm specialises also in standardised reflector fittings. All the Nitra lamps have "pipless" bulbs. A compact and useful list, giving very detailed dimensions both of lamps and lanterns, has been issued. Recent investigations in connection with these lamps are referred to on p. 417.

### Royal Ediswan Half-watt Lamps.

An attractive list has been issued by the Edison and Swan United Electric Light Co., Ltd., showing clearly the alterations in prices and the new sizes, and giving particulars also of the Goliath E.S. lamp-holders in two patterns, light and heavy; the former is of stamped brass, and suitable for interior use, and the latter is of heavy cast brass, substantially made and extra well finished, so that it is essentially the holder for exposed positions.

### Drake & Gorham.

Drake and Gorham, Ltd. (1 Felix Street, Westminster, S.W.), inform us that they have put in enormous stocks of half-watt lamps in anticipation of a large demand, and can guarantee delivery with their usual promptitude. They stock Osram, Mazda, Wotan, Ediswan, and Nitra lamps in all the voltages and wattages mentioned. For Osram half-watt lamps their terms of discount are the same as for standard Osram lamps; for other makes a preferential 7½ per cent. is given.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**ROTARY CONVERTERS.**—The General Electric Company, Ltd. (67 Queen Victoria Street, London, E.C.), have just issued a bulletin dealing with "Witton" rotary converters. The treatment of the subject is divided into three sections. The first section gives particulars of the construction, and is illustrated by photographs of the more interesting details. Section 2 deals with the general principles upon which the converters depend, and explains, without being too highly technical, the various factors which enter into the design. The third section deals very fully with the control of rotary converters. The various methods of voltage regulating, of starting and self-synchronising, all come in for treatment under this head. The fourth and last section relates to the operation of rotary converter sub-stations, and contains a good deal of useful information. There can be no doubt that any engineer who has to deal with this class of machinery will find this publication worth perusal.

**AUTOMOBILE AND BATTERY LAMPS.**—The British Thomson-Houston Co. (Mazda House, 77 Upper Thames Street, E.C.), have just issued a new price list of Mazda drawn wire automobile, battery, and flashlight lamps. This list comprises in the automobile section, head-light, side-light, tail-light, and steering pillar light lamps, and dome-light, festoon, and tubular lamps for interior lighting. A noteworthy feature is the inclusion of specially capped lamps for American cars. An important characteristic of these lamps is the helical coil or spiralled filament used in the head-light lamps, which gives a closer focus than can be obtained with any other practicable form of lamp. The list contains particulars of a number of miscellaneous types for battery service, such as motor-bus lamps, common battery lamps, illumination lamps, &c. Mazda flashlight lamps, both plain and opal back, are also listed at the reduced prices, and are now 6d. and 7d. respectively.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Australia.**—The Sydney Corporation requires 22,500 yds. of 33,000-volt three-core paper-insulated lead-covered cable. Copy of the specification may be seen at 73 Basinghall Street, E.C. Tenders by September 14th.

**Blackrock.**—Messrs. May and Hawes are reporting to the Council with regard to their electric lighting scheme.

**China.**—Electrical plant for the Tientsin Mint. Consulting Engineers, Sir Douglas Fox and Partners, 56 Moorgate Street, E.C. Tenders to Dr. Chen-Chin-Tao, Financial Commissioner, Chinese Legation, 49 Portland Place, W.

**Dublin.**—A loan of £80,300 for extensions to the electrical undertaking has been sanctioned. Of this sum £2,500 is to be expended on the conversion of public gas lighting into electric lighting. Originally the Corporation applied for £5,000 for public lighting, but this has been halved at the suggestion of the inspector.

**Edinburgh.**—The Secretary for Scotland has sanctioned the borrowing of £220,000 for electrical extensions.

**Grimsby.**—The Borough Electrical Engineer advises the installation of a new battery, switchgear, &c., at an estimated cost of £5,000. The carrying out of this scheme is urged upon the Corporation, as there is at present considerable risk of interruption in the supply.

**Hayle.**—An electric lighting scheme is under consideration. Power will in all probability be taken from the Cornwall Electric Power Co.

**London: Islington.**—A loan of £5,316 is recommended by the Finance Committee of the L.C.C. for additional cooling towers.

**New Zealand.**—An expenditure of £4,000 upon extensions to the electric lighting undertaking at Wairoa has been sanctioned.

**Rochdale.**—Twelve months' supply of paper-insulated cables. Borough Electrical Engineer. August 5th.

**Walsall.**—The Local Government Board has approved generally of the new power station, and has authorised the commencement immediately of urgent works.

### Wiring

**Hull.**—Tenders are invited for electrical fittings for the Council Chamber at the Guildhall. Town Clerk. August 22nd.

**Wisbech.**—Tenders are invited for the electric lighting of the workhouse. Clerk to Guardians, Union Offices, 2 Ely Place.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Arbroath.**—Building for Prudential Assurance Co.

**Brighton.**—Municipal concert hall (£25,000).

**Bristol.**—School at St. Philip's Marsh.

**Hastings.**—New hospital.

**Liverpool.**—New police courts.

**London.**—It is proposed to spend £350,000 on a new City Hall for Westminster.

**Portsmouth.**—Hospital for consumptives.

**Swansea.**—Five hundred houses. Town Clerk.

### Miscellaneous

**Canada.**—Tenders for the supply of 23 nauts of single-conductor submarine telegraph cable, to be delivered at Halifax, N.S., within eight weeks of ordering, and also for 14 knots of the same material, to be delivered at Vancouver, B.C., are required by the Department of Public Works, Ottawa. Copy of the specification may be seen at 73 Basinghall Street, E.C.

**South Africa.**—Tenders are invited for the supply of twenty-two electric motors of various sizes for the Salt River workshops of the South African Railways Administration. Further particulars at 73 Basinghall Street, E.C.

**Works Outing.**—The annual picnic of the Synchronome Co., Ltd., took place on Saturday last. The party, thirty in number, embarked at Windsor on the launch *Duchess* and visited Quarry Woods, Marlow, Bispham Abbey, and Temple Lock. Mr. Hope-Jones took an active part in the proceedings.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Harrogate.**—The tender of Goodbrand & Co. for a 288-pipe economiser has been accepted.

**London: L.C.C.**—The tender of G. Robson & Co. at £288 has been accepted for the supply of four portable electrically-driven drilling and grinding machines.

The following tenders have been received for 150 sets of plough collector gear:—British Westinghouse Co., £7 17s. 6d. per set; Brush Electrical Engineering Co., £7 19s. per set; Spagnoletti, £10 5s. per set; Estler Bros., £11 per set; Siemens Bros. Dynamo Works, £12 2s. 6d. per set. The first-named tender has been accepted at a total cost of £1,181 5s.

The tender of Drysdale & Co., at £178 12s. 6d., has been accepted for an electrically-driven vertical drainage pump. The Rees Roturbo Manufacturing Co. quoted £212, and the British Electric Plant Co. sent in an incomplete tender.

**Hackney.**—The following tenders have been received for 80,000 pairs of open-type white arc-lamp carbons:—The General Electric Co., 40,000 pairs at 70s. per 1,000, and 40,000 pairs at 60s. per 1,000; Henrion Carbons, Ltd., 68s. 11d. per 1,000 and 57s. 8d. per 1,000 respectively; H. Tuckman, 68s. per 1,000 and 57s. 6d. per 1,000. In view of the slight difference between the English and foreign prices, the Committee recommend the acceptance of the General Electric Co.'s tender. The highest price is for 18 mm. by 12½ in. cored carbons, and 13 mm. by 11½ in. solid carbons, whilst the lowest price is for 18 mm. by 10½ in. cored carbons, and 13 mm. by 9½ in. solid carbons.

The following tenders were received for 100,000 pairs of yellow flame arc-lamp carbons:—The General Electric Co., 62s. 6d. per 1,000; Electrical Co., 61s. 6d. per 1,000; Sloan Electrical Co., 60s. 6d. per 1,000; Ship Carbons, Ltd., 57s. per 1,000; W. Geipel & Co., 51s. per 1,000. In this case the Committee point out that the English carbons are so much higher in price that there is no reason to look beyond the lowest tender, viz., W. Geipel & Co., and this is recommended for acceptance.

Tenders were also invited for special higher grade carbons, but the prices are regarded as out of all proportion to the difference to which their use could make to the public lighting, and no recommendation is made with regard to these tenders.

**Stoke-on-Trent.**—The tender of Chamberlain & Hookham has been accepted for meters.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £62 15s. to £63 5s. (Last week, £63 5s. to £63 15s.)

**Canadian Agency.**—An electrical engineer at Montreal desires to get into touch with British manufacturers of steam turbines and high-speed electric generating sets, &c. Further particulars at 12 Victoria Street, S.W.

**Agency.**—Morris & Lister (London), Ltd. (8 and 4 Palace Chambers, Bridge Street, Westminster, S.W.), have now taken over the sole representation for London and the south of England for Mickelwright, Ltd., of Alpertown, in place of Mr. Raymond Smith, the late representative.

**Changes of Address.**—The Reliance Electrical Wire Co. (36 Spital Square, E.C.) have removed to Spitalfields Works, 38 and 40 Curtain Road, E.C.

Mr. C. H. Jeffcoat has removed to 18 Ranelagh Gardens, Chiswick, where inquiries for "Lamlok" specialities should be addressed.

**Works Holiday.**—We have received notice of closing of the following works for summer holidays:—A. P. Lundberg & Sons (477-489 Liverpool Road, N.), July 31st to August 10th; London Electric Firm (George Street, Croydon), August 1st to August 10th; J. H. Tucker & Co. (King's Road, Hay Mills, Birmingham), the whole of Bank Holiday week for the works, but offices and warehouse will re-open on the Wednesday; Western Electric Co., August 1st to August 10th; Liverpool Electric Cable Co., August 1st to August 10th.

**Reduction in Cable Prices.**—We regret that two inaccuracies occurred in the note on this subject on page 413 of our last issue. The discount on Henley's C.M.A. and Association flexibles, 2,500 megohm grade, should have been 33½ and not 33 per cent., and the special price for 3/22 non-Association Class W cable should have been £7 15s. instead of £9 15s.

**Agency.**—A firm of electric sign manufacturers in New Jersey desires to get into communication with United Kingdom makers of miniature metal-filament lamps; about 100,000 required. Further particulars at 73 Basinghall Street, E.C.

**Dissolution of Partnership.**—H. C. Barlow and H. A. Jackson, trading as H. C. Barlow & Co., 52 Chapel Street, Salford, have dissolved partnership. All debts will be paid by H. C. Barlow, who will carry on business at the above address.

## LOCAL NOTES

**Aldershot: Proposed Cooling Tower.**—A proposal by the Borough Electrical Engineer to erect a cooling tower at the electricity works, at an estimated cost of £400, met with considerable opposition at the last meeting of the Corporation, and eventually the matter was taken back by the Committee for further consideration. It was suggested by one member of the Council that a water tower is unnecessary, and that the same result could be effected by other means at a quarter the cost.

**Blackburn: Electrical Section to Chamber of Commerce.**—It has been decided to form an electrical section of the Blackburn Chamber of Commerce. Already several electrical firms are members of the Chamber, and the general body of the membership has passed a resolution agreeing to the new section. It may be mentioned that the Newcastle Chamber of Commerce has had an electrical section for some time.

**Bradford: Relief of Rates.**—Out of the net profit of £14,900 on the electricity undertaking last year, £5,000 have been contributed to relief of rates, £7,000 to expenditure of a capital nature, and the balance of £2,900 has been carried to reserve and renewals. The revenue for the year increased by £14,000, and the total number of units sold was 28,000,000, against 24,500,000 in the previous twelve months.

**Bristol: Satisfactory Progress of Electricity Undertaking.**—The annual report of Mr. H. Faraday Proctor, the General Manager of the Corporation's electricity undertaking, shows an exceedingly good result for the past year. The net profit amounted to £8,516, to which is added the balance of £2,411 from last year, making a total of £10,927. Of this £6,000 have been transferred to general reserve, new meters for renewals absorb £526, the final payment for the three-phase alternator at Avonbank takes £366, new meters on new connections cost £1,198, and wages of permanent workmen engaged on capital work not chargeable to loan account, &c., absorb a sum making a total of £8,613, leaving a balance of £2,314 to be carried forward. The year's accounts also take into consideration the reduction of £2,000 in the annual charge for public street lighting. There was a most gratifying increase in the general development, and the number of units sold increased by nearly 2½ millions, which, Mr. Proctor points out, taken in conjunction with the increase in the preceding year, shows a growth in the business of the undertaking of 50 per cent. during the past two years.

**Darwen: Electricity Accounts.**—The net profit on the electricity undertaking for last year was £972, against £912 in the previous year. This sum, however, remains after paying £1,000 to relief of rates, £70 to meeting the cost of switchboard improvements, and a further £500 in aid of the rates for the current year.

**Keighley: Electricity Profits.**—For the first time during its thirteen years' existence, the electricity undertaking shows a profit for last year running into four figures, viz., £1,200.

**London: St. Pancras: Large Electricity Profits.**—There was a net profit of £12,567 upon the electricity undertaking last year, to which is added the balance of £4,522 from the previous twelve months, making the credit of net revenue account £17,090. The sum of £4,000 is to be retained as working balance; the reserve fund now stands at £44,033, of which £30,610 is represented by loans advanced to the electricity capital account.

**Oldham: Electricity Accounts.**—The report for the past year of the late Mr. S. W. Newington, Borough Electrical Engineer, shows a net profit of £1,995, after meeting capital charges, and £1,215 expenditure on meters. This balance is

to be carried forward. Two G.E.C. 500-kw. motor-generators were put into commission on January 1st this year for the purpose of supplying extra high-tension A.C. current, and further tenders have been accepted for an extra high-tension A.C. switchboard and a 2,000-kw. high-pressure turbo-alternator and condensing plant, in order to meet the increasing demands upon the undertaking. The net profit is an improvement on that of the previous twelve months, when the amount was £1,044.

**Southampton: Electric Car.**—The Committee recommend the provision of an electric car for the use of the Borough Electrical Engineer. The Department propose to build this themselves, purchasing a chassis.

**Surbiton: Future of Electricity Undertaking.**—Under the present arrangement by which Callender's Cable & Construction Co. work the electricity undertaking on behalf of the Council, there is a loss of £360 per annum. A Sub-Committee which has been advised by Sir John Snell recommends the transfer of the undertaking to Callender's. The terms proposed are similar to those sanctioned by the Board of Trade in connection with the transfer of the Frome electricity undertaking to Edmundson's Electricity Corporation, and provide practically for a lease of the undertaking for forty-two years, at the end of which time the Council has the option to purchase. Messrs. Callender's will repay the deficit which has been incurred, in addition to paying off the debt charges, and will further pay the salary (fifty guineas per annum) of the consulting engineer whom the Council may appoint to watch over its interests. A recommendation to this effect was sanctioned at the last meeting of the Council.

**West Ham: Electricity Profits.**—In reporting a net profit of £751 on the electricity undertaking last year, Mr. J. W. Beauchamp, the Borough Electrical Engineer, calls attention to the fact that this is arrived at after meeting £7,550 increased cost of fuel, an increase in local rating amounting to £4,368, the purchase of new meters out of revenue, £809, cost of repairs on certain plant £1,200, and the equipment of the repair shop at a cost of £550, making a total of £14,477 out of revenue. Another satisfactory feature of the year's working is that the turn-over represents an increase of 7,000,000 units, or 25 per cent. over the previous twelve months. This additional output has been obtained with quite a moderate increase in the maximum demand on the plant, this resulting in an important addition to the load-factor, which is reflected in the total cost per unit. Lighting connections show a steady advance, and the development in power connections continues to be well maintained. The use of electricity for cooking is also developing rapidly, a number of electric cooking equipments in the staff kitchens of the large power users having been supplied.

**Wolverhampton: Electrical Exhibition.**—A very successful exhibition which was visited by 50,000 persons has been held by the Electricity Department on the occasion of the Annual Floral Fête, in a large marquee. A seven-roomed model house was arranged to demonstrate domestic applications; two large laundry companies also exhibited, and electrically-driven sewing machines were shown by Messrs. Singer's. Cooking appliances by a number of firms was exemplified, and demonstrations were given. A special sub-station was established to supply the exhibition, and a distributor board for 77 circuits was put up by the Department in forty-eight hours. Over 4,000 lamps were used outside for illumination purposes. Mr. S. T. Allen (Chief Engineer) has sent us some photographs showing the very effective nature of some of the stands.

## APPOINTMENTS AND PERSONAL NOTES

The late Sir Joseph Swan, F.R.S., left estate of which the net personalty has been sworn at £58,344. His electric and laboratory apparatus and appliances are, under the will, to be presented to any person, institution, or corporation which his executors may select. The sum of £100 is bequeathed to the Royal Society for defraying the cost of scientific publication.

Mr. E. S. Smith, Superintendent of the Finishing Department of the United Electric Car Co., Preston, has been appointed Assistant Engineer to Messrs. J. G. White & Co., in Pernambuco.

An Assistant Electrical Engineer is required in the Gun Carriage Factory, Jubbulpore, India. Salary, 280 rising to 320 rupees per month. Director-General of Stores, India Office, W.

## SUMMARY

WE give the details of the proposed central scheme for dealing with the supply of electricity in London. It is suggested that a Controlling Authority consisting of representatives of London and other boroughs around shall be formed, and that the actual work of centralising the supply of electricity would be placed in the hands of a new Company for a period of, say, fifty years, with full powers of control by the new Controlling Authority. (Page 428.)

AN interesting report by Dr. J. M. Beattie describes the apparatus for the electrical sterilisation of milk now successfully in use by the Liverpool Corporation and the experimental research work which led up to its establishment. (Page 429.)

A RECENT Paper read before the Royal Society by Sir Joseph Larmor and Mr. J. S. B. Larmor investigates the action of lightning conductors. (Page 429.)

AN illustrated article describes the arrangements for electrical driving at a wholesale chemist's factory. (Page 430.)

NOTES on the arrangements for the next session at some of the Universities and Technical Colleges are given on page 430.

A CURIOUS trouble on a motor circuit and the construction of electrolytic lightning arresters are dealt with in our Questions and Answers columns. (Page 431.)

THE specification for the "Coolidge" X-ray tubes was published last week.—Another specification published on the same date describes a system of wireless transmission invented by J. G. Balsillie.—Two B.T.-H. Co. patents for a motor-control system expire this week after a full life. (Page 432.)

TENDERS will shortly be invited for the supply of power for the Post Office tube railway.—The running of trailer and coupled cars on the L.C.C. northern tramway system is proposed.—The Hastings and District Electric Tramways Co. has been fined for having used the Dolter surface-contact system for three months beyond the time-limit allowed by the Board of Trade. (Page 433.)

MR. JUSTICE EVE has decided that the Helsby Wireless Telegraph Co. has infringed the Marconi Patent No. 7777 of 1900, which patent he has declared valid. There is to be an inquiry as to damages with costs against the Helsby Co.—The proposed agreement between the Board of Trade and Marconi's Wireless Telegraph Co. to be embodied in the Merchant Shipping (Convention) Bill has been abandoned, due to the protests by the shipping industry that they might have to pay monopoly prices for the apparatus under such an agreement.—Arrangements are being made for observations as to the effect of the solar eclipse on August 21st on wireless telegraph transmission. Five high-power stations, all using different frequencies, will send out special signals during the eclipse. (Page 433.)

A TRANSFORMER with an exceptionally low iron loss, which has been in satisfactory operation on the Continent for some time, is described in an illustrated article in our Trade Section, which also contains notes on various novelties. (Page 434.)

CONVERTING plant is required at Newport; an electrically-driven motor waggon at Belfast; a cooling tower at Birkenhead; a motor-generator at Oldham; and cable at Stalybridge.—8,000-kw. turbo-generators are to be substituted for the two remaining reciprocating engines at the Greenwich station of the L.C.C., and an expenditure of £18,500 is contemplated on cables.—Extensions are also to be carried out at Bristol (£42,000); Bury (£40,720); Farnworth (£3,400); Ilkley (£18,000); Wallasey (£64,500). (Page 437.)

THERE is an increase in the demand for hired electrical apparatus at Barrow-in-Furness.—The L.G.B. inspector has expressed himself unfavourably towards a proposal to pay the Redditch Borough Electrical Engineer a fee for acting as Resident Engineer in connection with extensions.—There was a net profit of ££8,677 on the Wolverhampton Electricity Department last year.—There was a considerable increase in the demand for electricity in Darlington last year. (Page 438.)

A 2 PER CENT. dividend is declared on the ordinary shares of the Yorkshire Electric Power Co., and 2½ per cent. by the Newcastle-on-Tyne Electric Supply Co. (Page 438.)

## FUTURE OF LONDON'S ELECTRICITY SUPPLY

### Unexpected Proposal by L.C.C. Committee.

THE Special Committee of the London County Council have, somewhat unexpectedly, already placed on paper their proposals for the concentration of London's electricity supply, and still more unexpectedly have put forward an entirely new policy. The first part of their proposal is obviously based on the correct principle, although possibly difficult of attainment. They intend that the three classes of electricity undertakings—viz., the fourteen companies which are purchasable on cheap terms by the L.C.C. in 1931, the fifteen undertakings which the Borough Councils can retain in perpetuity under the present law, and the various neighbouring company and municipal undertakings outside the County of London—should all be acquired by a new Controlling Authority, and combined on the lines suggested in Messrs. Merz and McLellan's report (*see ELECTRICAL ENGINEERING*, April 16th, 1914, p. 213.) It is the second part of the scheme that gives rise to some astonishment: namely, that the new undertaking thus formed should be leased to a company which is to provide part of the capital required for extensions, and this capital will apparently rank, so far as payment of interest and dividends are concerned, only after that provided by the Controlling Authority. The leasing company is to work under the general control of this Authority under certain definite restrictions, including the limitation of dividends.

On the method of bringing the new conditions into being, and the initial stages of procedure, the proposals are not very definite, and the Committee emphasise particularly that they have "aimed primarily at initiating a new policy rather than making any immediate revolutionary change in the *status quo*," and that the proposals which they submit are not intended to carry with them the "wholesale" scrapping of existing works. So far as it appears on the surface, however, no attempt has been made to ascertain whether the scheme would have the approval of the existing supply companies and the Borough Councils with electricity undertakings.

On the technical side of the question the Committee accept in their entirety the recommendations of Messrs. Merz & McLellan. The exact definition of the new area is not given, but it is stated that it will include portions of the areas of five other counties and three county boroughs in which there are thirty-nine municipal electricity undertakings and thirty-one companies. It is proposed that any powers of purchase by local authorities in the districts outside London should be transferred to the new authority, upon which the outer municipalities, as well as the London companies and L.C.C., would be represented.

The following are the details of the scheme:—

The leasing company, it is suggested, should at the outset be one which has control over a number of the existing undertakings, but "failing a sufficient number of existing companies coming forward it may be necessary to consider proposals by other bodies." With regard to finance, it is proposed that the Controlling Authority should advance by way of loan two-thirds of the capital required for fresh works, the remaining one-third being found by the company. All capital for the purchase of existing undertakings would be found by the Authority. A period of fifty years is suggested as the period of the lease to the new company, and the Controlling Authority would be empowered to resume possession after this period on repayment of the capital advanced by the company.

A technical committee consisting of a small number of engineering and financial experts, permanently appointed and paid for their services, is to be set up in the interests of the Controlling Authority, but emphasis is placed upon the necessity for preventing this control unduly hampering the company in its work. It is suggested that the Authority should exercise the following important powers of control:—(1) Approval of all proposals by the company involving capital expenditure. (2)

Approval of the nature of the capital raised by the company and of the terms on which that capital is raised. (3) During the last ten years of the lease, approval of all agreements and contracts entered into by the company. (4) A scale of maximum charges by the company for energy supplied, to be revised by the Board of Trade from time to time upon the application of either the Authority or the Company. (5) Powers to take action for the protection of the interests of retail and bulk consumers. (6) Such general controlling powers as are now possessed by the L.C.C. under the Electric Lighting Acts and the London Electric Supply Acts of 1908 and 1910, &c., to be transferred to the Authority, with certain necessary exceptions. (7) An auditor to be appointed by the Authority to act with one appointed by the Company.

No compulsory purchase of the Borough Council undertakings is entailed, and although it is regarded as in favour of the scheme that interference with existing undertakings will be reduced to a minimum, no recommendation is made in respect of those undertakings which the local authorities could refuse to lease or sell. This, however, is evidently provided for by the suggestions made for maintaining co-operation and interworking between the new company and the existing undertakers. In this portion of the scheme it is provided that local authorities who are authorised distributors in the area of supply are to be required to take from the new undertaking any additional power required by them, if it can be shown to the satisfaction of the Board of Trade that it would be more profitable for them to do so than to extend their own plant. Although the company is to be authorised to raise capital, it will not have power to charge the assets of the undertaking. A sinking fund is to be established, vested in the Authority, upon the basis of the capital expenditure in connection with the undertaking being written off as follows:—Land and engineering works, 60 years; cables, 40 years; power stations and sub-stations, with plant, 25 years; services, 12 years; interest paid out of capital, 30 years; purchase of existing undertakings, 30 years.

The net revenue from the undertaking is to be dealt with as follows:—(1) the payment of interest at 4 per cent. per annum on the proportion of capital found by the Authority; (2) the provision of a sinking fund to be owned by the Authority at the rate of about 2 per cent. per annum on the whole of the capital of the undertaking; (3) the payment of interest on the capital found by the Company at 4 per cent. per annum; (4) the provision of a reserve fund calculated at 1½ per cent. per annum on the whole of the capital of the undertaking; (5) the division of any surplus profits equally between the Authority and the Company until the Company receives a share sufficient to pay a further 4 per cent. interest upon its capital expenditure, making 8 per cent. in all. Of any profits beyond this, 75 per cent. is to be utilised in giving rebates to the consumers, and the remaining 25 per cent. is to be divided equally between the Authority and the Company.

The "Conclusion," with which the report terminates, almost suggests that the Committee anticipate that the scheme is still-born. They say:—

The keynote of the whole proposal is that it is an offer to the existing undertakings of a means of increasing the efficiency of their present undertakings, or, if they prefer it, an offer of a means of handing over their complete undertakings, upon terms to be agreed, to a central authority.

The precise details of the scheme, with a definite recommendation to the Council to promote legislation next session, are to be placed before the Council after the summer recess; the actual date proposed is November 3rd.

There was a long agenda to be got through at the meeting of the L.C.C. on Tuesday night, and (we believe by agreement beforehand) the reception of the Committee's report was also postponed to after the summer recess. As the Bill to give the Council the powers sought would have to be drafted early in November to enable it to come up for consideration next session, it is therefore questionable whether a Bill to give the Council the necessary powers can be drafted and deposited for this session. If it will be too late for this, the present report has brought us no nearer to the solution of the problem of the future of London's electricity supply.

## ELECTRICAL PURIFICATION OF MILK

**A**N interesting report by Dr. J. M. Beattie, City Bacteriologist at Liverpool, deals with the electrical treatment of milk, and describes a long course of laboratory research on the subject, and the large scale electrical milk treatment installation now in use at the Corporation Milk Dépôt in Earle Road, which was the outcome of those experiments.

The earliest experiments that were made by Mr. F. C. Lewis in the Thomson-Yales Laboratories of the Liverpool University consisted in passing unidirection currents through the milk, but it was found that not only was the required sterilisation not produced, but that undesirable changes were produced in the composition of the milk. Unidirection and slowly alternating currents were tried with milk to which minute quantities of salt had been added, but although this was successful from the sterilisation point of view, the milk was still spoiled from the consumer's point of view by the chemical changes in its constitution. In this method part of the salt is decomposed, as also is a part of the water, and an unstable body of high disinfecting power is produced. In subsequent experiments a rapidly alternating current was used with the addition of salt, and it was found that by this means the bacterial content of the milk could be reduced to a minimum, while the chemical constitution of the milk was apparently unimpaired. Although only in rare cases was the milk rendered absolutely sterile, it was freed from dangerous or disease-producing bacteria and from the ordinary milk-souring bacteria, and there was an enormous reduction in number of all other forms of bacterial life. The actual reduction was over 99 per cent. In the original experimental

SECTIONS OF ELECTRODE CHAMBER IN STERILISING TUBE.

apparatus a long glass tube was used, with three bulbs along its length, into which electrodes were sealed. The central electrode was connected to one pole of a transformer, and the two outer ones in parallel with the other pole, but in the improved form of the apparatus, upon which the design of the large permanent equipment was founded, separately constructed electrode chambers were used, connected up by rubber joints. A report by Mr. W. H. Roberts, City Analyst, confirms that the chemical composition of the milk is unaltered, and gives evidence of the non-increase of acidity and the improved keeping power of the milk. Mr. Roberts also states that the lactalbumin which is coagulated in ordinary sterilised milk is not coagulated in the electrically-treated milk, nor are the enzymes destroyed. Feeding experiments on kittens also demonstrated that the nutritive value of the milk is not impaired.

These experiments were so satisfactory that steps were at once taken to establish a larger plant at the Corporation Milk Dépôt, Earle Road, Liverpool. A large tank is provided, capable of holding a full day's supply of milk. This is connected with a smaller tank, in which the milk can be maintained at a constant level by a ball valve. From this the milk flows by gravity through the sterilising tube to receiving tank, from which it is conveyed to the bottling apparatus. The electrical apparatus consists of an alternator driven by a D.C. motor, a step-up transformer, and the necessary control gear. The transformer is kept in a fireproof chamber, and the sterilising tube is in a glass-fronted cupboard, interlocked with the switchgear, so that it cannot be opened when the current is on. The sterilising tube is provided with three electrode chambers, each supported in detachable brass claws fitted on to a brass back plate, through which the high-tension cable passes before it enters a vulcanite case,

in which it is connected to a spring terminating in a flat circular disc. The vulcanite case is covered by a vulcanite cap, and surrounds the upper part of the glass electrode chamber. This contains a nail-headed copper electrode, making contact with the spring disc. The arrangement is shown in the figure. These fittings are carried on a slate slab. For purposes of safety the milk passes through aluminium tubes before and after passing through the steriliser. These tubes, as well as certain other parts of the apparatus, are earthed. With the aluminium electrodes used at first trouble was sometimes experienced, due to flashing at the central electrode, especially when the rate of flow slowed down. This gave the milk a burnt taste, but this has been practically overcome by the use of copper electrodes. Small testing tanks are, however, provided, so that milk thus charred can be prevented from getting into the main supply. Exhaustive tests indicate equal success of this plant to that of the laboratory apparatus. The current used is slightly over 2 amperes at about 4,000 volts, and no undue heating effect is produced. Independent reports by Professors Delépine, Ritchie, and Sims Woodhead fully confirm Dr. Beattie's observations as to the improvement in keeping qualities and reduction in bacteria of all kinds, and the total suppression of *bacillus coli* and its allies.

## LIGHTNING PROTECTION

**A**N interesting study of lightning discharges and the effect of lightning conductor systems is contained in a Paper recently read before the Royal Society by Sir Joseph Larmor, F.R.S., and Mr. J. S. B. Larmor. The authors investigate the nature of the lightning discharge, and conceive of the flash commencing at some point in the field where, owing to the displacement of charged masses of the wind and by their mutual attractions, the limit of dielectric strength is reached, when a breakdown occurs and the disruption spreads along the line of force both backward and forward from this point of most intense force. In the case of a lightning rod they believe that the discharge starts at the summit of the rod, which is the point of most intense strain, and really strikes away from the rod and not towards it. The zigzag character of many flashes is due to the fact that the discharge profoundly alters the fields of force between the clouds and neighbouring masses, thus inciting immediate new discharges. Something of this kind is indicated by the discontinuous crackle of a sharp discharge. When once an ionised path is opened up, there is a strong tendency for subsequent discharges to take place along it. Sometimes the ionised line is blown into a new position by the wind, which may account for the frequently photographed parallel flashes. The authors then proceed to investigate the region of protection of a lightning rod by considering the modification of the field of force due to its influence. As a general principle it is the building to which the rod is attached that modifies the field and draws the charge by virtue of its conducting materials on account of its breadth being substantial compared to its height. The structure protects the region around its base by directing discharge to its own copper parts, which therefore need protection by conductors adequate to draw off the discharge to earth and vertical rods joined together if need be lower down, but rising from the corners of the structure to a height which need not be more than about half its breadth. The rods may rise from a network spread over the roof, and their essential feature appears to be their lifting the field of intenser force to the region in which their free ends are immersed. A lightning rod is most effective when it lies along the lines of force. Horizontal connecting rods are only of use when the charge is oblique.

**40,000-h.p. Turbo-alternator.**—The largest turbo set yet constructed on the Continent is now under test in the Mannheim works of the Brown, Boveri & Cie., A.-G. It is rated at 40,000 h.p., and has been constructed for the Kommunale Elektrizitätswerk Mark, A.G., in Hagen. The set runs at 1,000 revs. per min., and generates at 10,000 volts, 50 cycles. Including the condensing plant, the weight is 385 tons. The turbine is supplied with superheated steam at 350° C. and 12.5 atmospheres, and has a thermal efficiency of 22 per cent. The consumption is given as 0.612 kg. pounds of coal per kw. hr., with a boiler efficiency of 83 per cent.

**"The Central."**—The July issue of the magazine of the old students of the City and Guilds (Engineering) College opens with an excellent portrait of Dr. W. E. Sumpner, and contains an illustrated article entitled "The Production of an Engineering Newspaper," in which an idea is given of the work involved in preparing and producing ELECTRICAL ENGINEERING. Other articles deal with telegraph experiences in Tibet and tests of Humphrey gas pumps.

## ELECTRIC DRIVE IN A WHOLESALE CHEMISTS' FACTORY

RELATIVE to its size, a wholesale chemists' and druggists' factory calls for a fair amount of electrical power. Cleanliness is naturally of the utmost importance in such work as is here carried on, and this fact, together with the diversified points at which power is required, render an electric drive particularly advantageous. An installation which has been laid down on model lines is found in the factory of

FIG. 1.—ELECTRICALLY-DRIVEN MIXERS AND DISINTEGRATORS.

Messrs. Wilkinson & Simpson, of Newcastle-on-Tyne. In this factory power is used for driving mixing vats employed in the preparation of metal polish and sauces, and for driving bark disintegrators used in the preparation of medicines, for the mixing of health salts, baking powder, and other similar products. In the proximity of the grinders and mixers there is naturally a certain amount of fine dust, though not suffi-

FIG. 2.—INTERIOR OF MOTOR HOUSE.

cient to make it necessary to enclose the motors totally. The "Witton" motors for the most part are enclosed in glass houses, several motors being grouped in one house wherever possible. The motors are fixed sometimes on the ceiling, but more usually on brackets projecting from the wall, and drive through belting. The switchgear is mounted on the wall, and is readily accessible. A view of the drive for mixers

and disintegrators is shown in Fig. 1; the motor house can be seen on the right-hand side with the door open. Its cleanliness and attractive arrangement are well shown in Fig. 2, which is taken looking upward from the door of one of the large motor houses. This motor house contains four motors of 18 h.p., 15 h.p., 7½ h.p., and 6 h.p. respectively. Not all the motors are employed for driving on the floor, from which the view is taken, but operate machinery on the floor above by means of belting. In addition to the purposes previously mentioned, electric drive is also used for the working of hoists and a number of ventilating fans, a considerable number of motors of similar size to those mentioned above being utilised in various parts of the works. The installation throughout reflects considerable credit upon the contractors responsible for its installation—Messrs. T. Toward & Co., Ouseburn, Newcastle-on-Tyne. The motors and switchgear for this factory were constructed by the General Electric Co., Ltd., of Wotton, Birmingham, and 67 Queen Victoria Street, London, E.C.

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE South-Western Polytechnic, Manresa Road, Chelsea, will re-open on September 28th, for day classes, and on September 21st for evening classes. The Electrical Engineering courses include practical instruction in the fully-equipped laboratories, and students are prepared for the London B.Sc. degree in Engineering, for the examinations for admission to the various Engineering Societies, and the examinations of the City & Guilds of London Institute. The evening courses include classes in Electrical Wiring, and in this department an advanced course has been arranged for the preparation of candidates for the Final Wiremen's Examination of the City & Guilds of London Institute. Arrangements are made for placing students who have passed satisfactorily through the three years' day course in positions with large engineering firms. The prospectus may be obtained, price 1d., at the Institute, or by post, 4d.

The next session at the Engineering Departments of the University of Leeds will commence on October 5th. Mr. G. D. Aspinall Parr is Head of the Electrical Engineering Department. Full particulars of the courses can be obtained from the Secretary.

Special facilities are given for research work in Electrical Engineering at King's College, London. Among the subjects of special courses of advanced lectures which have been arranged are "The Commercial Aspect of Electrical Engineering" and "Central Station Practice and its Relation to Legislative Enactments." The courses of instruction in Electrical Engineering prepare students for the diploma of King's College and B.Sc. Engineering degree of the University of London. The entrance examination begins on Monday, September 21st, 1914. Full information and syllabus may be obtained from the Secretary or from the Dean of the Faculty of Engineering.

The 125th Award of Prizes at the Crystal Palace School of Practical Engineering takes place to-day, Mr. A. G. Lyster, President of the Institution of Civil Engineers, in the Chair.

**Electric Fire-escapes in Berlin.**—Over half of the Fire Brigade vehicles of Berlin are now power-driven. Of the 74 power-driven vehicles, 48 are electrically propelled, the remaining being petrol vehicles. From the report for the past year, the *Berliner Tageblatt* notes that the electric vehicles have run a total of 62,200 miles or 1,300 miles per vehicle. The cost of upkeep works out very considerably lower than that for horse vehicles. For a complete group of four electric vehicles, the average annual cost, including cost of charging over a period of six years, has been £277 or £69 5s. per vehicle. The annual cost for a horse-driven group of four similar vehicles is £1,095, or £273 15s. per vehicle—that is, sufficient for the upkeep of four electric vehicles. As a result, a saving of over £20,000 has been effected in just over three years in the upkeep of eight groups of each four vehicles. A still greater saving will be effected, as in future all repairs will be carried out in the fire brigade's own workshops. It is also expected that the price for current for charging will be reduced considerably below the present figure of 1.8d. per kw.-hr. At present the batteries are charged every four weeks to preserve the plates against sulphating, but it is hoped that this will be reduced to once every 8 weeks. It will be remembered that some notes on the use of electric vehicles in the London Fire Brigade were given by Lieut. Sladen in the discussion at the Institution of Electrical Engineers in March (*ELECTRICAL ENGINEERING*, March 26th, page 175). The cost of working appears to be lower in Germany than here, but a direct comparison is not possible, as the German costs given above do not apparently include depreciation.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,402.

The writer is interested in the electric driving of reversing rolling mills, and would like to know if the Föttinger hydraulic coupling in conjunction with a high-speed motor has been proposed, and, if so, how do the results compare with a direct-coupled or gear-driven arrangement. How would the coupling behave with such a peaky load as a rolling mill. The writer believes that this patent coupling can act in either direction. If so, a continuously running motor could be used, possibly enabling a Ward Leonard set to be dispensed with. The writer has in mind rolling mills of fairly large size, those in which the continuous rating of the motors is, say, 1,000 h.p. and upwards.—"COUPLING."

(Replies must be received not later than first post, Monday, Aug. 10th.)

### ANSWER TO No. 1,398.

A three-phase slip-ring motor generator, 400 h.p. 2,200 volts, is loaded about 35 per cent., and is supplied from a distant power station  $2\frac{1}{2}$  miles away, through aluminium lines 37/12 S.W.G. The motor runs satisfactorily until another motor of 300 h.p. is switched in circuit, when a heavy thump is heard shaking the foundation and breaking the bridge connections of rotor winding each time the second motor is switched in; this machine is controlled with reversing switch, and is 500 yds. further away. The thump is not heard in the motor when switching on the motor-generator. The starting current of the motor is about 50 amps. at 2,200 volts.

Can I do anything to prevent this heavy thump?—DEAD EARTH.

An award of 10s. has been made for the following reply from "M."—

"Dead Earth" does not give sufficient information to enable one to say definitely what the cause of the trouble is likely to be, but it appears to be caused by the sudden switching on of the second motor setting up a surge in the circuit. The reason why the same thing does not occur when the motor generator is started up after the 300 h.p. machine may be due to the fact that the conditions of the circuit, as regards capacity and inductance, are different, and it is only under certain con-

ditions that a severe surge is likely to be produced. The way to overcome this trouble is to bring the current up more gradually by switching on through a resistance, in much the same way as in a D.C. motor; it is, however, usually sufficient to provide only one step. This may be done by providing the control switch with a set of auxiliary contacts, and connecting

the resistance between the main and the auxiliary contacts in such a way that in the act of closing the switch the resistance is first put in circuit and then short-circuited. A suitable resistance in this case would have a value of about 25 ohms (twenty-five), and should be rated to carry about 30 amps. for one second. The resistance may be of carbon powder in earthenware troughs, such as is supplied by the Morgan Crucible Co., or may be of high resistance carbon rod such as is used for lightning arresters, or it may be a metallic resistance wound non-inductively. The diagram shows how the resistances should be arranged in each phase.

### ANSWERS TO No. 1,400.

In connection with aluminium electrolytic lightning arresters, what is the electrolyte (giving a critical A.C. voltage of about 300) that is generally used? Is it true that only one wave of the alternating current produces the insulating film by converting the aluminium in hydroxide, while the opposite wave has no effect? Also, is it necessary to form the film or even part of it before assembling the aluminium trays?—"ARRESTER."

A first award of 10s. has been made to "A. G. T. C." for the following reply:—

The exact composition of the electrolyte used in lightning arresters of the electrolytic type is usually regarded as something of a trade secret by the manufacturers. The properties of an electrolytic lightning arrester are due to the characteristic of a film of aluminium hydroxide formed on a plate of aluminium by electrolytic methods. The plates are usually sent out by the manufacturers with the films already formed, but as a precaution against damage in transit, the operation is performed again after erection. This is done by connecting a 250-volt A.C. circuit between every two plates successively, sufficient lamps being in circuit to limit the current to about 2 amps. If the films are in order, the lamps will burn dimly, but if not, the lamps will be bright, gradually becoming dim as the films form. Both waves of the A.C. current are effective, one half on one plate and one half on the other. If D.C. current is used, it should be reversed for each cell. The film slowly dissolves in the electrolyte, so that the forming operation should be carried out if the arrester is out of service for some time. In practice it is usual to bridge the horn-gaps in series with the arrester once a day.

The second award (5s.) is made to "A. L.," whose reply is given in slightly abridged form below:—

The composition of the electrolyte is not, as a rule, stated by the makers. The aluminium cones as received from the manufacturer have the film of aluminium hydrate partially formed, so must be very carefully handled, by the rim only, when assembling in stacks. After filling the cones with electrolyte, the cells should be tested by putting about 300 volts A.C. across each in succession. Connect a resistance in series sufficient to limit the current flow to about 2 amperes with cell shorted out, so as to limit the current flow if the film of hydroxide is not fully formed. It is convenient to put lamps in series as a resistance, then they burn brightly with unformed cells, but as the film thickens up they glow dimly. The latter indication will be given at once if the film is fully formed, or if the cell is empty of electrolyte, which can readily be noted. If only a D.C. source of supply is available at the time of "forming," it must be applied first in one direction, then in the reverse polarity, as both A.C. waves have a "forming" effect, and it is necessary, therefore, to "form" on both sides of the aluminium cones. "Forming" of the film before placing the arrester on the line is necessary to limit the charging current required, which would otherwise be excessive and liable to set up dangerous surging. After filling up the arrester cones, they should be put in service as soon as possible, because the electrolyte has a solvent action on the film when standing idle.

[The actual composition of the electrolyte in the lightning arrester is, as our correspondents say, not made public by the makers. A patent for a lightning arrester of this type (No. 6,872/09) was allowed to lapse this month, as announced in our Patent Record on July 16th, and this gave the following recipe: Six parts of boric acid are added to one part of tartaric acid and the mixture neutralised by adding sufficient ammonium hydrate. Ten per cent. of glycerine is now added and the resulting acidity of the solution is again neutralised by the addition of more ammonium hydrate. As the patent has been allowed to lapse, this is probably not the exact electrolyte now employed.—ED. E.E..]

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published July 23rd, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

14,892/13. **Vacuum Tubes.** B.T.-H. Co. (*G.E. Co., U.S.A.*). The remarkable feature of these tubes is that instead of their action depending upon the ionisation of the gas contained in the tubes, every effort is made to exclude all trace of gas from the interior, and the current is carried from the cathode to the anode by electrons emitted from the heated cathode. The latter consists of a flat spiral of tungsten wire which may be conveniently heated from an independent source of current. By adjusting this current, the "hardness" of the "X" rays emitted from the tube can be regulated at will. The anode, which also serves as a target for the electrons, consists of a flat disc held on a stem and sealed into one end of the bulb. Both stem and disc should be preferably of wrought tungsten. A focusing device for ensuring stability of the focal point is also included. It consists of a hollow cylinder of suitable conducting material located inside the tube, round the cathode and electrically connected to the latter. Eight figures. (See also ELECTRICAL ENGINEERING, June 25th, p. 369.)

15,673/13. **Wireless Telegraph Transmitter.** J. G. BALSILLIE. The radiator circuit is electrostatically coupled, i.e., through condensers, to the charging circuit, and is energised by unidirectional excitation. The charging circuit, comprising capacity and inductance, is synchronised with a primary circuit, including an A.C. generator. A portion of the charging circuit is bridged by a rectifying discharge gap, adjusted so that no high-frequency oscillations can occur in the exciting circuit, so formed. One of the electrodes of the gap has a central hole through which air is forced, at a pressure of about 100 lb. per sq. in. The radiating circuit, which may or may not be provided with tuning inductance, has considerable capacity, so that it is itself capable of oscillating. The advantages claimed are that the aerial radiates its own pure wave, and that the radiating power is very high. Thus with a primary energy of 3 kw. it has been found possible to radiate 1½ kw. Four figures.

18,355/13. **Arc Lamp Electrodes.** B.T.-H. Co. (*G.E. Co., U.S.A.*). This invention consists in employing a lithium compound such as borate, fluoride, or oxide as a steadying material in white arc light electrodes. In the case of titaniferous electrodes it is found that the addition of the lithium compound increases the intensity of the light produced, so that the invention also includes the addition of a lithium salt to such electrodes as an intensifying agent even if other steadying materials are also present. A satisfactory electrode has been made by mixing 96 per cent. of finely powdered titanium carbide with 3 per cent. of black copper oxide and 1 per cent. of lithium fluoride in a thin iron tube.

## Specifications Published To-Day

The following Patent Specifications will be published to day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** BARKER (Thompson Electric Co.) [Hanger for h.t. lamps] 16,791/13; KORN [Operation of intense current arcs] 4,230/14; AYRTON [Carbons] 6,104/14; KORTING & MATHIESEN AKT.-GES. [Vapour lamps] 11,644/14.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** PETERSEN and KEMP & LAURITZEN [Distant control] 16,152/13; WATKINS [H.T. insulators] 3,150/14; DESPESAILLES [Lighting installations] 7,938/14.

**Dynamos, Motors, and Transformers:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Motors for ships] 15,199/13; BOERRIES [Motor supports] 15,554/13; LUCAS and MOORE [Dynamo-electric machines] 16,015/13; GARDE & KOEFOED, HAUBERG MARSTRAND & HELWEG AKTIE-ELSKABET TITAN [Winch motor] 20,135/13; SIEMENS SCHUCKERTWERKE GES. [Commutator A.C. machines] 2,409/14.

**Electrometallurgy and Electrochemistry:** GOLDSCHMIDT AKT.-GES. [Rail welding] 25,179/13; FRIED KRUPP AKT.-GES. [Cooling of furnace electrodes] 6,731/14.

**Heating and Cooking:** PERRY [Heating apparatus] 11,937/14. **Ignition, &c.:** FORD [Magneto] 15,656/13; HARTFORD [Engine starter] 19,524/13; KETTERING and CHRYST [Ignition systems] 6,072/14.

**Incandescent Lamps:** SIMPSON [Manufacture of tungsten] 15,297/13; SWINBURNE [Vehicle lamps] 19,985/13.

**Instruments and Meters:** CHURCHWARD [Pyrometers] 15,922/13. **Batteries, &c.:** ACHENBACH [Galvanic cells] 10,616/14.

**Switchgear, Fuses and Fittings:** KETTERING and CHRYST [Switches] 7,545/13; SIEMENS BROS. DYN. WKS., LTD., and BOLTON [Blow-outs] 17,712/13; GEIPEL and MARGERISON [Resist-

ances] 1,248/14; TORCHIO and WOODROW [Circuit-breakers] 10,004/14.

**Telephony and Telegraphy:** LOPEZ and CREED, BILLE & Co. [Telegraphy] 15,561/13; PINTER [Telephone call meter] 15,675/13; BROWN [Telephony] 15,828/13; ORLING and ORLINGS TELEGRAPH INSTRUMENT SYNDICATE, LTD. [Duplex telegraphy] 16,268/13; BARWELL and EASTERN TELEGRAPH Co. [Duplex telegraphy] 16,435/13; RAYMOND-BARKER [Telegraphs] 27,225/13; NIGRON [Printing receivers] 1,548/14; WESTERN ELECT. Co. (*Woodward*) [Telephone receivers] 1,968/14; GRAHAM and RICKETS [Telephone systems] 6,097/14.

**Traction:** JOHNSON and THORROWGOOD [Railway signalling] 13,064/13; A.E.G. [Current collectors] 5,594/14; SOC. ANON. DES AUTOMOBILES ET CYCLES PEUGEOT [Lighting system] 9,175/14; CARDWELL [Signalling systems] 11,516/14.

**Miscellaneous:** JOYCE & SPAGNOLETTI, LTD. [Safety-lamp igniter] 17,529/13; ALLISON [Illuminated fountains] 22,765/13; MASCHIN-ENFABRIK OERLIKON [Electro-hydraulic presses] 26,340/13; A.E.G. [Ticket printing machine] 6,332/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Arc Lamps:** LEWIS [Carbons] 22,222/13; CONRADTY [Carbons] 22,223/13.

**Dynamos, Motors and Transformers:** AKT.-GES. BROWN, BOVERI ET CIE [Rotary converter] 24,305/13.

**Electrometallurgy and Electrochemistry:** CASELLA [Manufacture of electrodes] 14,582/14.

**Incandescent Lamps:** RENAULT [Headlights] 15,052/14.

**Telephony and Telegraphy:** GILES [Condensers] 10,868/14, 11,404/14; A.E.G. [Condenser connections] 15,580/14.

**Miscellaneous:** MEYER [Vacuum-tube apparatus] 15,399/14.

The following Amended Specification may now be obtained:—

**Traction:** S. L. PRICE [Dynamos for vehicle lighting] 19,345/12.

## Opposition to Grant of Patents

6,806/13. **Regenerative Motor Control.** CROMPTON & Co., LTD., and H. BURGE.

19,857/13. **Anti-Vibration Lampholder.** F. H. REEVES. The Comptroller has decided to allow the grant of these two patents.

## Expiring and Expired Patents

The following Patents expire during the current week, after the life of fourteen years:—

13,721/00. **Motor Control System.** B.T.-H. Co. (*C. L. Perry*). This system is particularly applicable to electric trains, where two or more motors are to be operated by series-parallel controllers having a number of separately actuated contacts. The coils for actuating these contacts are connected to the master controller so that they may be connected in series and operated from the line potential. When only a few coils are in operation an additional resistance is introduced into the circuit to prevent an excessive current. The advantage of this arrangement is that whilst only a small current is drawn from the line for energising the coils, the latter need not have so high a resistance as would be necessary if they were operated in parallel across the line. This enables considerable economies of space and material to be effected. Eight figures.

13,975/00. **Motor Control System.** B.T.-H. Co. (*C. L. Perry*). This invention applies to the same class of work as the preceding one, and has for its object the reduction of the number of conductors between the master controller and the other controllers. The actuating coils for the contact devices are connected across every pair of conductors, thus enabling as many contact devices to be actuated from a given number of conductors as there are combinations of such conductors taken two at a time, i.e., with  $n$  conductors  $n(n-1)/2$  contacts could be actuated. Three figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** A. H. ARMSTRONG [Motor control system applicable to induction motors working in tandem] 22,279/01; F. BASENAU [Insulating compound] 8,071/02.

**Dynamos, Motors and Transformers:** M. PFATISCHER [Motor control by use of interpoles] 7,286/05, 7,286A/05.

**Ignition:** H. L. MAILLARD [Magneto] 2,694/05; CHAMBERS MOTORS, LTD., and A. M. PATTON [Magneto] 7,747/08.

**Incandescent Lamps:** P. M. JUSTICE (*Deutsche Gasglühlicht Akt.-Ges.*) [Filament supports] 8,499/06.

**Switchgear, Fuses and Fittings:** J. WILSON [Automatic cut-out] 25,224/09.

**Telephony and Telegraphy:** W. P. THOMPSON (*Ges. für Drahtlose Telegraphie*) [Wireless detector] 8,659/06; R. K. GRAY [Method of loading cables] 8,419/09.

**Miscellaneous:** H. A. CAMPICHE [Clocks] 7,211/05.

## ELECTRIC TRACTION NOTES

The Hastings & District Electric Tramways Co. has been fined £5 for continuing to use the Dolter surface-contact system along the sea front for three months beyond the time-limit allowed by the Board of Trade. The police took action against the Company on account of the reports that pedestrians had received shocks, and that three horses had been killed. The Dolter cars have now been replaced by cars driven on the Tilling-Stevens petrol-electric system.

There has been considerable feeling on the part of drivers in the employ of the L. & S.W. Ry. Co. at the possibility of their positions being jeopardised by the introduction of electric traction. After much discussion the Railway Co. has agreed that the whole of the engine-drivers and firemen at present employed on steam trains shall be engaged on electric trains at their present rates of pay, and that they will be offered positions in order of seniority, subject to them being qualified. The cause of the trouble was that the Company had appointed men of other grades than locomotive engineers and firemen as motormen on the electric trains.

The Post Office tube railway was referred to in the House of Lords on Thursday, when Lord Newton asked if tenders had been invited for the supply of electric power. Under the Act dealing with the railway, the Post Office is prohibited from supplying itself with power for this railway, if it can obtain it cheaper elsewhere, and Lord Strachie, on behalf of the Government, said that there was no intention of neglecting the obligations imposed by the Act. Lord Sydenham expressed the opinion that it would be unwise, in view of the unsettled state of electric supply generally in London, to embark on a new installation for the purposes of the railway.

The Highways Committee of the L.C.C. recommends application being made to Parliament next session for authority to enable the Council to run trailer and coupled cars on the tramways north of the River Thames. Under the Council's Act of 1912, the use of trailer cars on the south of the river was restricted to certain routes, but the Board of Trade has since sanctioned their use on almost the whole of the southern system.

Interim dividends are declared by a number of London electric railway companies. The Metropolitan District Railway Co. recommends the full dividends on the 4 per cent. guaranteed stock and the  $4\frac{1}{2}$  per cent. and 3 per cent. preference stocks; 4 per cent. is recommended on the preferred ordinary stock of the Central London Railway Co., and 1 per cent. on the ordinary shares of the London Electric Railway Co. No dividend is recommended on the ordinary shares of the City & South London Railway Co., but the full preference dividend will be paid.

An issue of 70,000 six per cent. £1 preference shares has been made by the Northern General Transport Co., which was recently formed, and has now a controlling interest in the Gateshead & District Tramways Co., the Tynemouth & District Electric Traction Co., and the Jarrow & District Electric Traction Co.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

On Friday, July 25th, Mr. Justice Eve delivered judgment on the Marconi v. Helsby Wireless Patent case. It will be remembered that the plaintiffs, Marconi and Marconi's Wireless Telegraph Co., claimed damages from the Helsby Wireless Telegraph Co. in respect of four wireless installations on ships belonging to the L. & N.W. Ry. The difference between the defendants' apparatus and that described in Marconi's Patent No. 7,777/00 was the inclusion of two extra spark gaps and a through charging coil (see diagrams in ELECTRICAL ENGINEERING, July 2nd, p. 381). His Lordship held that whilst these two gaps did shorten the main spark, yet this did not make the action of the apparatus fundamentally different from that of Marconi's apparatus. The real question was: "Is it an essential feature of Marconi's invention that the primary should continuously feed the secondary during the whole period of radiation?" This he found not to be the case. In the defendants' apparatus the primary built, and for a time

maintained, the oscillations of the aerial circuit. It was therefore substantially the same as was covered by the claims of Specification No. 7,777/00, and was an infringement. Regarding the plea of invalidity which was put forward by the defendants, the Judge found that neither the writings of Tesla or M. Ducretet taught the world the substance of Marconi's invention. The Patent was therefore valid. Judgment was accordingly entered in favour of the plaintiffs, who are entitled to an inquiry into the amount of damages due in respect of the infringements. Defendants are to pay costs of the action.

Arrangements are now well advanced for the observations for investigation of the effect of the total solar eclipse on August 21st on wireless telegraph transmission, when five high power stations at St. Petersburg, Bobrouisk, Norddeich, Paris, and Nauen, all using different frequencies, will send out special signals during the eclipse. That at Bobrouisk will be situated within, St. Petersburg to the east, and the others to the west of the path of the umbra. A full programme has been issued, and forms to be filled up by observers have been prepared. It is desired in particular to investigate the influence on the strength of the signals crossing the shadow, of the re-combination of the ions due to the withdrawal of the ionising sunlight, and to determine how quickly these actions take place. Experimenters in wireless telegraphy possessing such apparatus of precision as will enable them to make accurate measurements are invited to communicate with Mr. W. Duddell, F.R.S., 56 Victoria Street, S.W. Prospective observers willing to make aural estimates of signal strength, or to make observations on strays (either by the Graphic Record method, or by the method of registering the number heard during every thirty seconds) should send an intimation to that effect, with a notification of which portion of the observations they could undertake, to the Hon. Sec., B. A. Radiotelegraphic Committee, 88 Gower Street, W.C. They should also state the number and the names of those of the five sending stations with which it would be most convenient for them to work.

According to *The Times* Shanghai correspondent, the new wireless station on the Telefunken system at Woosung is complete. This station is one of six provided for in an agreement last year. Three others have also been completed, and those at Swatow and Hankow remain to be erected. In this connection it is of some interest to remember that an agreement is in contemplation between the Marconi Co. and the Chinese Government for the erection of wireless telegraph stations.

During the consideration of the Merchant Shipping (Convention) Bill by the Standing Committee of the House of Commons last week, some discussion took place with regard to Clause 17, which deals with the provision of wireless apparatus on ships in relation to a proposed agreement between the Board of Trade and the Marconi Co. for the supply of wireless telegraph apparatus and operators to mercantile shipping. The shipping industry was strongly averse from this agreement on the ground that they might have to pay monopoly prices for the apparatus, and this objection was expressed before the Committee very emphatically by Sir Henry Norman, Sir Croydon Marks, and others. The President of the Board of Trade said that the negotiations had been entered with the Marconi Co. with a view to arriving at some reasonable working agreement which would protect shipowners against unfair or arbitrary prices for the supply of apparatus. Eventually, however, the amendment to Clause 17, embodying the proposed agreement, was withdrawn.

Owing to the political disturbance on the Continent, telegraphic conditions have been unsettled. Already on Monday private telegrams for Austria and Hungary had to be written in plain language, viz., German, French, English, or Italian, and Hungarian was also authorised for messages to Hungary. Neither trade marks nor commercial terms were, however, admitted. Telegrams without text or containing military intelligence were prohibited. Later telegrams to Germany, Austria, Hungary, Bosnia-Herzegovina, Roumania, and Bulgaria were subject to delay owing to failure of lines and pressure of business. The Hungarian administration, on the strength of Article 7 of the St. Petersburg Convention, advised that partial restrictions were established on telegrams, i.e., until further notice private telegrams in code and cipher, containing exchange prices in figures, commercial marks, and those without text were prohibited. Any telegrams had to be written in Hungarian, Croatian, German, French, English, or Italian. Censorship was established generally and telegraphic communication between Hungary and Serbia was suspended. On Tuesday, however, telegrams for Serbia could be sent *via* Great Northern Company *via* Russia and Roumania at 5d. per word, and *via* Russia and Bulgaria at 6d. per word, and another route *via* Eastern and Salonica was also available at 6d. per word. Up to yesterday afternoon these routes were still open. Notice of delay to Germany has been cancelled.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 437. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**"FREEZOR" FANS.**—For the use of electrical contractors who are keeping abreast of the times by making a speciality of "Freezers" during the hot weather, a neat folder has been designed by the General Electric Company, Ltd. In it are given several cogent reasons for adopting these fans in offices, shops, restaurants, and the home. The fact that the fans are entirely British made is a point that will probably appeal to a large number of prospective purchasers. The company will be pleased to send a supply of the folders to any contractors on application.

**HEATING AND COOKING.**—The Edison and Swan United Electric Light Co., Ltd. (Ponders End, Middlesex), has just issued a catalogue dealing with the well-known "Ediswan" heating and cooking specialities. Practically all the usual types of apparatus, such as kettles, grills, ovens, and hot plates for cooking, and irons, domestic and industrial, are included. An ingenious combined lamp carrier and adapter, which is particularly suited for use with irons, is also described.

**TELEPHONE APPARATUS.**—A useful catalogue has been issued by Siemens Bros. & Co., Ltd. (Woolwich, S.E.). It covers a wide range from inexpensive house telephones to C.B. and automatic exchange switchboards. Among the novelties, we notice a new type of vacuum lightning arrester arranged inside an ebonite insulator for fastening on the overhead line at the point of junction with the underground cable. The "hand-com." instruments for house telephones have all terminals inside so that the necessity of threading the cord through the stem is obviated, and a detail of interest in the exchange boards is that the cords are fitted with a patent spiral steel protector, which, it is said, increases their life fourfold.

**ELECTRIC SIGNS.**—A most artistically produced booklet gives some very suitable advice to contractors and others on electric signs, and illustrates some very attractive patterns supplied by Simplex Conduits, Ltd. (Garrison Lane, Birmingham).

**TELEPHONES.**—A comprehensive list of telephones and accessories is to hand from the Edison & Swan United Electric Light Co., Ltd. (Ponder's End, Middlesex). An extensive range of domestic and inter-communication sets are included,

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

as well as battery and magneto instruments for public and private lines or for longer distances. Other specialities are mining telephones and special metal-cased instruments for hospitals and other large institutions. Electric mine exploders are dealt with in the same catalogue.

**FANS.**—A very tastefully executed brochure from the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), contains an illustrated description of the company's large electric fan works at Witton, Birmingham, where the popular and excellent "Freezor" fans are manufactured in very large quantities. Some descriptive notes on this works were given in *ELECTRICAL ENGINEERING*, June 11th, page 323.

**METERS AND CONTROL GEAR.**—A leaflet from the Electrical Apparatus Co., Ltd. (Vauxhall Works, South Lambeth Road, S.W.) calls attention to some of the company's latest designs of E.A.C. high-torque house service meters, motor-starters, and control gear.

**MOTOR-STARTERS.**—A number of patterns of autotransformer starting panels for squirrel-cage induction motors are dealt with in a new collection of price sheets from George Ellison (Victoria Works, Warstone Lane, Birmingham).

**USES FOR ALUMINIUM.**—This forms the subject of a neat little booklet issued by the British Aluminium Company, Ltd. (109 Queen Victoria Street, London, E.C.), showing the advantages of employing aluminium for a great variety of purposes, ranging from the manufacture of aeroplane propellers to that of candlesticks. Amongst the electrical applications may be mentioned underground and overhead power transmission, switchboard and battery connections, and magnet windings for electrical machinery. It is interesting to note in regard to this that the weight of an aluminium conductor is only half that of a copper conductor with the same current-carrying capacity.

**FLAME ARC LAMPS.**—A booklet issued by Crompton & Co., Ltd. (Chelmsford, Essex), describes their open-type Crompton-

Blondel flame arc lamps. Particulars of the burning conditions for various sizes of lamps are given, and we note that these have been revised in accordance with the latest investigations. The number of burning hours obtainable per trim has been increased in many cases. Particulars are also given of the raising and lowering gear, choking coils, auto-transformers, and other accessories.—Another leaflet from the same company relates to their enclosed arc lamps, which can be supplied to burn in parallel, in series, or in series parallel on A.C. or D.C. circuits. Two types are manufactured, viz., "Single Carbon" and "Twin Carbon." The former are designed to burn singly or in series, allowing 100 volts per lamp, whilst the latter burn singly on 200/250 volts.

**INTERLOCKED SWITCH AND PLUG.**—A leaflet from the Adnil Electric Co., Ltd. (Artillery Lane, E.C.), describes a continuous switch fuse and earthing plug in dust-proof cast-iron case, arranged so that the plug cannot be withdrawn unless the switch is off, nor can the switch be put on unless the plug is in.

### THE "SMIT" TRANSFORMER

SOME very good results have been obtained from the "Smit" three-phase oil-cooled transformers which are being introduced into this country by Mr. E. E. St. John (Queen Anne's Chambers, Westminster, S.W.). The drawing below shows the internal construction of the 1,250 k.v.a. size, several of which, we understand are in satisfactory operation on the Continent. The cores and yoke

FIG. 1.

are built up of paper-insulated, silicon steel stampings with exceptionally low hysteresis factor. A section of one of the cores can be seen in Fig. 2. It will be noticed that the corners are stepped back, so that in winding the coils, sharp corners are avoided. Stout angle irons and insulated bolts are used

## "Prana" Die Castings

will **lighten your costs** very considerably.

They leave the dies in a **finished, ready-**

**for-use state, accurate** to a degree only obtainable (by other methods) by long and costly "micro-machining." In addition to this **each one is an exact duplicate of all the others**—and so all die cast parts are **automatically interchangeable**, but they must be "**Prana.**"

**AERATORS Ltd., UPPER EDMONTON, N.**

**Ladders, Steps, Trestles, Scaffolds, &c.**

Sale or Hire.

**HEATHMAN & CO.**

10, Parson's Green, London, S.W.

**MARRYAT & CO.**

**DYNAMO & MOTOR HOSPITAL,**

28, MATTON GY LONDON, E.C.

**PHENIX**  
**ASSURANCE COMPANY, LIMITED.**  
 ESTABLISHED 1782.

Head Offices: 19 & 70, LOMBARD STREET, LONDON, E.C.

TOTAL FUNDS EXCEED	CLAIMS PAID EXCEED
<b>£16,000,000</b>	<b>£90,000,000</b>

CHAIRMAN: RT. HON. LORD GEORGE HAMILTON, P.C., G.C.S.I.

**FIRE - LIFE - ACCIDENT - MARINE**

Loss of Profits following Fire, Workmen's Compensation, Fidelity Guarantee, Burglary, Trustee and Executor, &c.

**ELECTRIC LIGHTING.**

The Company has always encouraged the development of Electricity, and the well-known "Phoenix Fire Office" Rules for Electrical Installations are in use throughout the world. Copies will be supplied free on application to Head Offices.

General Manager: SIR GERALD H. RYAN.

Gbonite.

VULCANITE WORKS:  
**Dr. HEINR. TRAUN & SONS,**

(Formerly HARBURG INDIA-RUBBER CO.)

London Warehouse  
**F. WINTER, 25 Goswell Road, E.C.**

Vulcanite.

for pressing the yokes together, and as can be seen in the drawing, this ensures great strength combined with simplicity. The case is of welded sheet-iron with a comparatively light cover which can be removed for inspection or to enable the inter-connections of the windings to be altered if required.

The windings, which are not shown in the drawing, are of

FIG. 2.—1/10 Size.

the cylinder type, the high-tension windings being situated directly outside the low-tension windings and separated from them by insulating material. A test on the above transformer gave the following results:—

Primary voltage	...	10,740
Secondary voltage	...	2,000
Frequency	...	50 cycles per sec.
Full-load iron loss	...	5,250 watts
copper loss	...	11,200 watts
efficiency	...	98.7 per cent.

The insulation test was 22,000 volts, alternating, applied between high and low tension windings and between high-tension windings and core, and 5,000 volts between low-tension windings and core for one minute.

The chief point of interest in these figures is the low iron loss, and in consequence the high efficiency at light loads.

## AMPERE HOUR METERS AND CIRCUIT BREAKERS FOR AUTOMOBILES

A FORM of ampere-hour meter which can be used on electric cars to indicate the amount of charge remaining in the battery at any moment, and can be interlocked with a circuit to prevent overcharge, is described in a booklet from Edison Accumulators, Ltd. The Sangamo ampere-hour meter, for which the Company are sole British agents, is in almost universal use in America, and is of very great utility to the driver. In its usual form a pointer moving forward for discharge and backward for charge over a circuit scale reads direct in ampere-hours, and an integrating mechanism can be provided to record the total amount of charge, a very useful addition from the cost-keeping point of view. Special relay contacts control the circuit-breaker, which is tripped when a full charge has been received, and in one form of the instrument the dials can be placed at a different part of the car from the actuating mechanism. The meter itself consists essentially of a small electric motor with its moving system completely immersed in mercury in a non-spilling chamber. The construction is substantial, and the apparatus is in every way fit to stand the shocks of roadwork. The circuit-breaker has a simple electro-magnetic trip, and is provided with auxiliary contacts which break the tripping circuit. The apparatus is largely used in America for train-lighting batteries, as well as for automobile work.

## A SEALING-WAX HEATER

WE illustrate here a new pattern of electrical sealing-wax heater which has been introduced by Simplex Conduits, Ltd. (Garrison Lane, Birmingham), and is finding extensive application in post offices, banks, &c. The wax container is

SEALING WAX HEATERS.

of cast-iron, and this is supported from the wall by means of a rigid bracket arranged so that the container comes well over the table. There are two outlets for the wax, each operated independently by lever handles. There is a heat insulating pad interposed between the container and the bracket. Two sizes are made, for 250 and 400 watts respectively.

ALL OTHERS BOW BEFORE  
*The*  
**'CRYSELCO'**  
METAL FILAMENT LAMP.

## SMIT TRANSFORMERS

**RELIABILITY. LOW IRON LOSS.  
CLOSE REGULATION.  
GOOD OVERALL EFFICIENCY.  
COMPETITIVE PRICES.**

Sole Agent for the British Empire:—

**EDWARD C. ST. JOHN, M.I.E.E.**  
Queen Anne's Chambers, Westminster, LONDON, S.W.  
Telephone: Victoria 6196. Telegrams: "Switchonia, London."  
CODE—A.B.C., 5th Edition.

### A HUGE CONSIGNMENT

THE notice on the side of the motor waggon illustrated here is self-explanatory. This consignment left the British Thomson-Houston Co.'s stores at Mazda House, Upper

Thames Street, at 6 p.m., on Thursday, July 9th. Nothing that could be said here would add to the impressiveness of the inscription on the lorry.

### A NEW TOWER LADDER

THE illustrations herewith show a new telescopic ladder tower designed by Mr. Heathman, the experienced maker of Parsons Green, London, for use at Bexley Heath. It is fitted with tall wheels to travel upon ordinary roads, and also flanged wheels for tram rails, with brakes to operate upon both sets of wheels. The extension section adjusts at intermediate heights, and is surmounted with a guard-rail and tool table, while plumbing jacks are provided to set the tower vertical for use upon a hill. The construction is well braced to secure durable rigidity, and a coupling bar is fitted to attach behind a tramway car.

**Sizes of Half-Watt Lamps.**—By a printer's error, the sixth line in the voltage column in the table of sizes and prices of half-watt lamps on page 422 of our last issue was set at 200 to 255, instead of 100 to 130. The standard sizes of half-watt lamps for 100 to 130 volts are 200, 300, 500, 1,000, and 1,500 watts.

**G.E.C. Sports.**—On Saturday, July 18th, the Witton Athletic Club held their annual sports at Witton. These are open to the whole of the G.E.C. organisation, and large contingents of competitors came from the branches and works in all parts of the country. Over 50 came from Cardiff, and Osram Lamp Works contributed a strong team. Amongst the valuable prizes were the Hallgarth Cup for the 100 yards race, the Byng Cup for the best relay team, the Directors' Cup for the department showing the best athletic prowess, and a magnificent trophy, the Hirst Cup, for the finest G.E.C. athlete. The Directors' Cup was won by Section 5 of Witton Works (Switchgear Department, Arc Lamp Department, Export Department, and Publication Department), and one of their number carried off the Hirst Cup. The Byng Cup was gained by Osram Lamp Works, and the tug-of-war by the Witton Engineering Department. At the conclusion of the sports Mrs. Railing presented the prizes.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Belfast.**—Electric motor tower waggon. City Electrical Engineer. August 24th. (See advertisement on another page.)

**Birkenhead.**—An open-type water-cooling tower with 100,000 gallons per hour capacity is required. August 10th.

**Bristol.**—A loan of £42,000 is recommended for requirements in connection with mains, sub-stations, and services during the next three years.

**Bury.**—Sanction has been received to a loan of £40,720 for extensions at the electricity works.

**Eastbourne.**—Additions to switchboard. Borough Electrical Engineer. August 18th.

**Farnworth.**—A Local Government Board inquiry has been held concerning a loan of £1,900 for plant and £1,500 for prospective expenditure on mains.

**Ilkley.**—The Local Government Board has sanctioned a loan of £18,000 for electrical extensions.

**London: Battersea.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £3,275 for electrical extensions.

**St. Pancras.**—The Finance Committee of the L.C.C. recommends sanction to a loan of £22,530 for a 5,000-kw. turbo-alternator, &c.

**Stepney.**—The Finance Committee of the L.C.C. recommends sanction to loans of £35,000 and £3,000 for electrical extensions.

**L.C.C.**—Following the substitution of turbines for a number of the reciprocating engines at the Greenwich power-station, the Highways Committee has now recommended a similar substitution of turbines for the two remaining reciprocating engines. The estimated cost of two 8,000-kw. steam turbo-generators, additional condenser water piping, &c., is put at £88,000. In making this recommendation, the Highways Committee points to the increase in load on the power-station which will follow the additional trailer cars now being put into operation, and when additional through-running arrangements are completed. The installation will include four induced-draught fans for the B. & W. boilers, which are strongly recommended by Messrs. Kennedy & Donkin, the Council's Consulting Engineers. The recommendation was passed at Tuesday's meeting.—There is also to be an expenditure of £18,500 for cables.

**Newport (Mon.).**—Converting plant. Borough Electrical Engineer. August 17th. (See advertisement on another page.)

**Oldham.**—A D.C. motor-generator is required; extensions are to be carried out to the H.T. switchboard. Town Clerk. August 16th.

**Stalybridge.**—The Joint Tramways and Electricity Board requires a supply of E.H.T. three-core, lead-covered insulated cable. Engineer-in-Chief.

**Wallasey.**—The Local Government Board has sanctioned the borrowing of £64,500 for the new power station.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Bury.**—Police station. County Architect.

**Cork.**—Warehouse in Hanover Street. Architects, Chillingworth and Leve, 11 South Mall.

**Dundee.**—Cinematograph theatre.

**Eccles.**—New co-operative stores.

**Edinburgh.**—Electric lighting of proposed Mining Rescue Station. Clerk, Heriot Trust, 20 York Place.

**Leek.**—Houses in Shirburn Road. (The Corporation is specially extending the mains.)

**Wellingborough.**—Factory and offices for Ideal Clothiers, Ltd. Architects, Sharman & Archer.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Dublin.**—The tender of the General Electric Co. has been accepted for both prepayment and ordinary meters, upon the terms of their existing contract.

**Keighley.**—Tenders for a 750-kw. rotary-converter and transformer at £1,595, and two water-tube boilers at £5,067, have been accepted.

**Leeds.**—A tender for a 13,000-kw. turbo-alternator and condensing plant at £34,160 has been accepted, subject to the necessary sanction to the loan.

**London: L.C.C.**—The Fire Brigade Committee recommends the acceptance of a tender by Mossay & Co., at £807, for an electrically-driven chassis for carrying a turntable ladder. If this chassis is satisfactory, an additional one will be ordered within three months at £727, or two at £1,389.

The following tenders have been received for rotary converters: Dick, Kerr & Co., at £13,065 10s.; Bruce Peebles & Co., £13,092; British Westinghouse Co., £14,196 5s.; General Electric Co., 14,261; The B.T.-H. Co., £14,377; Siemens Bros. Dynamo Works, £16,274. The tender of Dick, Kerr & Co. is recommended for acceptance.

The following tenders have been received for static transformers: British Electric Transformer Co., £5,695; B.T.-H. Co., £5,916; British Westinghouse Co., £6,166 and £6,011 (alternative); Johnson & Phillips, £6,419 12s.; Bruce Peebles & Co., £7,005; Siemens Bros. Dynamo Works, £8,420. The tender of the British Electric Transformer Co. is recommended for acceptance.

**Salford.**—A contract has been placed with Chamberlain & Hookham for meters.

Among contracts recently placed with E. Bennis and Co., Ltd., are two chain grates for Wimbledon, two stokers with self-cleaning compressed air furnaces for Burton-on-Trent, and two chain-grate stokers for Altrincham.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £60 10s. to £61. (Last week, £62 15s. to £63 5s.)

**Works Holidays.**—We have received notice of the closing of the following works for summer holidays: Edison & Swan United Electric Light Co. (Ponders End), August 1st to August 10th; Electrical Apparatus Co., Ltd. (Vauxhall Works, South Lambeth Road, S.W.), Electromotors, Ltd. (Openshaw, Manchester), and Balcke & Co., Ltd., August 1st to 9th.

**Change of Telephone Number.**—The telephone number of the British Thomson-Houston Co.'s premises at Mazda House, 77 Upper Thames Street, E.C., has been changed to Central 10434 to 10438. Two additional lines have been installed.

**Power Gas Corporation.**—Mr. J. F. Pasley, of the Head Office of this firm, has been appointed representative for Lancashire, with headquarters in Manchester. Mr. F. G. Fogg, late North-East Coast representative, has been appointed London representative at 39 Victoria Street, S.W.

## APPOINTMENTS AND PERSONAL NOTES

The King has conferred the distinction of the Honorary Knight Grand Cross of the Victorian Order upon Mr. G. Marconi.

Mr. A. M. Kissack, Charge Engineer at the Stoke-on-Trent power-station, has resigned. By a re-arrangement of the staff the vacancy is to be filled without advertising for a successor. Mr. A. T. Gilbride has been appointed Charge Engineer, at a commencing salary of £120, with two increments of £5 per annum; Mr. H. V. C. Cotton has been appointed Charge Engineer at the Longton Works, at a salary of £2 per week, and Mr. J. Bickerton has been appointed Shift Engineer at the Burslem Works at £1 12s 6d. per week.

Mr. W. H. Dixon, of Southampton, has been appointed Chief Lecturer in the Electrical Engineering Department at the Salford Technical Institute (in succession to Dr. W. G. Rhodes, resigned), at a salary of £225, rising to £300 per annum.

Mr. R. P. Yates, of Gillespie & Beales (Amberly House, Norfolk Street, Strand, W.C.), was married to Miss D. Liddetter, at Halifax, on Thursday last. A canteen of cutlery and table silver was presented by the staff of Gillespie & Beales and the British Electric Equipment Co.

The Station Engineer and Mains Superintendent at Aberdeen have been granted increases of salary of £25, making £250 in each case.

A Shop Foreman is required by Burnands, of Sheffield. (See advertisement on another page.)

### LOCAL NOTES

**Barrow-in-Furness: Hiring-Out Apparatus.**—In his annual report for the past year (we gave the figures relating to the undertaking in our issue for June 18th, p. 354), Mr. H. R. Burnett, the Borough Electrical Engineer, states that the demand for apparatus on hire continues to increase, and that the rentals obtained leave a substantial balance after paying all expenses, and providing for depreciation on a liberal scale. Attention is also called by Mr. Burnett to the scheme of supplying small houses, of which he spoke at the I.M.E.A. Convention when discussing Mr. Bowden's Paper (ELECTRICAL ENGINEERING, June 25th, p. 365). The progress of this system has been accelerated at Vickerstown by an arrangement with the Isle of Walney Estates Co.

**Carlisle: Deficit on Electricity Undertaking.**—A deficit of £200 on the past year's working of the electricity undertaking, against a profit of £1,500 in the previous twelve months, was reported at the last meeting of the Council. This result, however, was more or less anticipated at the commencement of the year in consequence of the increase in the price of coal, the enormous increase in rates, together with increases in wages. At the same time, it is not felt that the position is one for serious alarm, and it is certainly not one for which the Engineer can be blamed. The Chairman of the Electricity Committee paid a tribute to the manner in which the works have been maintained, and also pointed out that the units sold, the maximum demand, and the income were the highest in the history of the undertaking. Furthermore, the Chairman expressed the fullest confidence of the Committee in the Engineer, and the soundness and ultimate success of the undertaking.

**Darlington: Increase in Electricity Output.**—The Electricity Committee reports a satisfactory increase in the units sold last year, compared with the previous twelve months. The increase for lighting was 18 per cent., and for power purposes 30 per cent.

**Grassington: Water Power v. Oil Engines.**—Owing to interruptions in the supply caused by the insufficiency of water at the power station, the local electric lighting company, which has hitherto depended upon water supply for driving its generator, is installing an oil-engine.

**Keighley: Plant Extensions.**—In connection with the acceptance of the tenders referred to in our "Tenders Received and Accepted" column, several members of the Council voted for an amendment to refer this back for further consideration, and also in order that outside expert opinion should be obtained upon the electrical undertaking generally. The amendment, however, was lost.

**Oldham: The Late Mr. S. W. Newington.**—At the last meeting of the Electricity Committee, the Chairman paid a high tribute to the ability and capability of the late Mr. S. W. Newington during the many years he had held the position of Borough Electrical Engineer. He emphasised the fact that it would not have been necessary to call in an outside expert with regard to the electrical undertaking, but for Mr. Newington's illness.

**Port Glasgow: Electric Supply.**—It is anticipated that the laying of the necessary cables by the Greenock Corporation for supply in this district, will be completed within the next three or four months.

**Redditch: L.G.B. and Resident Engineer.**—At the recent L.G.B. inquiry the Inspector expressed himself unfavourably towards a proposal that the Borough Electrical Engineer should receive a special fee of £300 as remuneration for acting as Resident Engineer under Messrs. Handcock & Dykes, the

Consulting Engineers, during the extension works to be carried out. In consequence of this the Council has rescinded the resolution to pay this sum of money, and an arrangement has been made with Messrs. Handcock & Dykes to remunerate the Borough Electrical Engineer for acting as their Resident Engineer for the extensions.

**Wolverhampton: Progress of Electrical Undertaking.**—A net profit of £8,677 is shown by the accounts of the electricity undertaking for the past year, in spite of an increase in the cost of coal and an increase in the assessment, the latter creating an additional burden of £1,000 per annum. Of the balance available it is proposed to transfer £2,125 to relief of rates and place the remainder to reserve.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Newcastle-on-Tyne Electric Supply Co.**—An interim dividend of 2½ per cent. has been declared on the ordinary shares.

**County of Dorset Electric Supply Co.**—This company, which was formed some time ago to supply electricity in Lyme Regis, Dorchester, Swanage, and Blandford, has not yet got into full working order. Nevertheless, the results to date are fairly satisfactory, the number of consumers in the four towns being 256, notwithstanding that two of the undertakings have only been in operation a short time, and that one is not yet working. The directors contemplate issuing a further £15,000 capital to meet the requirements of the company.

**Yorkshire Electric Power Co.**—The full interim dividend on the 6 per cent. preference shares has been recommended, together with 2 per cent. on the ordinary shares.

### NEW COMPANIES

**UNITED STATES RAILLESS ELECTRIC TRACTION CO.,** Finsbury Pavement House, E.C. Capital £1,000.

**BACHELET LEVITATED RAILWAY SYNDICATE, 11,** Waterloo Place, S.W. Capital £50,000. To enter into an agreement with Emile Bachelet. It will be remembered that the Bachelet Levitated Railway, Ltd., was registered a short time ago, and issued a prospectus, but did not go to allotment owing to lack of support.

**ELECTRICAL SALES PROMOTION,** Craven House, Kingsway, W.C. Capital, £1,000. To prepare and design advertising and other trade literature for dealers in electrical goods and appliances, &c.

**BRITISH ELECTRICAL ACCESSORIES, 17 and 19 Facet Road, Bradford.** Capital, £1,000. To take over the business of an electrical supplies factor carried on by C. Pullan at 80 King's Parade, Bradford.

**ECONOMIC ELECTRIC, 64 London Road, Twickenham.** Capital, £10,000. To take over the existing business of the Economic Electric Co.

**Electrical Fatalities.**—A man named C. A. Gale received a fatal shock at the Cornbridge Road sub-station of the Cardiff Corporation Electricity Department last Thursday. The man, who was well accustomed to the class of work, was coupling up low-pressure leads to a transformer in a pit, and in endeavouring to make a sharp bend in the cable (which, of course, was dead) he forced it against a temporary high-pressure cable, doing mechanical damage to the latter and so receiving the full 2,500 volts. The effect was made all the worse by the fact that he was leaning against the earthed transformer tank. Unfortunately he had his thumb on the brass thimble at the end of the low-tension cable. Had he held it a little lower, probably he would have been protected by the insulation. Rubber gloves were provided for him, but as he was not at the time working on a live cable he did not consider it necessary to use them. We understand that this is the first fatal accident since the inception of the undertaking.

On Saturday last a man named A. W. Harris, who was working on a 5,000-volt switch panel making alterations without having had the panel made dead, touched a live part and received a fatal shock at the works of the Eyelet Co., Nechells, Birmingham.

Another fatality occurred on Tuesday of last week at the North Eastern Marine Engineering Co.'s Works, South Dock, Sunderland, when P. Cornforth, in starting an electric hammer, accidentally touched some 240-volt terminals which were unprotected, contrary to the Factory Regulations.

## SUMMARY

THE limiting temperatures for the safe working of generators and transformers are discussed in the Questions and Answers column. (Page 440.)

FROM the district reports of the Inspectors of Mines we gather that nearly half the mines in the kingdom use electric power, and that motors aggregating over 500,000 h.p. are installed. The use of electric safety lamps is rapidly increasing, nearly 40,000 being already employed. There were 18 fatal accidents due to electricity during 1913. (Page 441.)

THE equipment of a Yorkshire colliery in which electric power is used exclusively is described. (Page 442.)

ANOTHER article describes the electrical equipment of a Scottish colliery. (Page 442.)

DEMONSTRATIONS have recently been given with a new form of electrical fire-damp indicator. (Page 442.)

A NEW system of audible and visual mine shaft signalling designed to comply with the new regulations is described. (Page 443.)

AMONG the subjects of patent specifications of interest to mining electrical engineers published during last month are electric safety lamps combined with gas detectors and signalling apparatus for haulage work. Several specifications relating to electric furnaces have also been published. (Page 443.)

AN illustrated article describes an explosion-proof circuit breaker for mining work. (Page 444.)

SOME notes are given on the C.M.B. system of electric colliery main shaft winding. (Page 444.)

A MEMBER of the Institution of Electrical Engineers proposes the formation of a register of electrical engineers willing to undertake emergency Government service. (Page 445.)

THE Patent Specifications published last Thursday include a system of electric ship propulsion. A method of preparing tungsten for lamp filaments, a method of controlling meter switches, and a system of bus-bar protection by reactances. (Page 446.)

A VERY ingenious design of circuit breaker with thermal time limit control is described. (Page 447.)

THE new automatic signalling equipment on the Central London Railway presents several points of interest. (Page 447.)

ALL wireless telegraph service is now in the hands of the Government.—We describe some experiments in the control of fog signals by wireless.—Telegraphic communication to and from the Continent is considerably disorganised, and there is censorship and delay. The use of codes is prohibited in most cases.—A committee of technical experts is at present considering the question of high-speed telegraphy. (Page 448.)

WE give an illustration of the new Ediswan show-rooms in our Trade Section, in which a new form of metal filament lamp and a train-lighting equipment are also described. (Page 449.)

ROTARY-CONVERTERS are required at Sunderland; an electric organ-blowing equipment at Southport; street-lighting apparatus at Brighton; new generating plant at Grimsby (£30,000); a large quantity of meters in Australia; mains at Walsall; and plant extensions at Cleckheaton (£8,000). (Page 450.)

AN important report has been made upon the Southampton electricity undertaking by Sir John Snell, who endorses the policy hitherto advocated by Mr. Street, the Borough Electrical Engineer, including the charge of ½d. per unit for cooking, &c.—The dispute between the electrical contractors and the Southport Electricity Committee still continues.—Complaint was made last week that the Liverpool City Electrical Engineer had accepted a fee for services rendered to a neighbouring authority.—Satisfactory progress is reported by a number of municipal electrical undertakings for last year, and the question of the relief of rates from profits is still the subject of much difference of opinion. (Page 452.)

WE are not publishing our usual fortnightly cartoon to-day.

**Export of Carbons Prohibited.**—A proclamation published in the *London Gazette* yesterday prohibits the exportation from Great Britain of searchlight carbons.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1403.

In a trolley scheme erected on steel girders with an overhead trolley and return rail system, the rail is connected to the negative of the dynamo. Total length of track 500 yards. What should be the maximum drop? What tests should be carried out to ensure that the leakage current is not excessive, and what is the best type of indicator or recorder to instal, so that records of the leakage current can be taken? There are a large number of gas mains in the neighbourhood of this trolley.—DOCTOR.

(Replies must be received not later than first post, Thursday, August 13th.)

### ANSWER TO No. 1,401.

As a charge-engineer of a generating station, what would you consider the minimum temperature of the coils of a generator or transformer at which you should report that something was wrong? (A) In the case of cotton insulation. (B) In the case of mica or micanite insulation.

The first award (10s.) is made to "W. H." for the following reply:—

**D.C. Generators, Cotton Insulated.**—It would only be possible to take temperature readings on the field coils. After continuous running at full load, the temperature on the fields would be approximately 40° C. above the atmosphere. Most electrical manufacturers would guarantee 25 per cent. overload on their machines for a period of two hours, and this would produce a temperature rise of approximately 55° C., so that any temperature rise above this would indicate either a serious overload, or that part of the shunt winding had become short-circuited. Assuming the latter not to be the case (this would be indicated by bad operation); it would not be wise to allow the temperature rise to go any higher than about 65° C. This, with an atmosphere temperature of 25° C., would give an actual temperature of 90° C., and cotton will actually char if kept at a temperature of 90° C. for any length of time.

It is, of course, impossible to obtain mica insulated small wire suitable for shunt field windings.

**A.C. Generators with Revolving Armatures.**—These would come under the same ruling as above, excepting where a bar-wound mica insulated field winding was used, and in such cases the permissible temperature rise could be increased to 75° C. Assuming an atmospheric temperature of 25° C., this would give a resultant temperature of 100° C., which would not be injurious to the mica, but would indicate very serious overloading.

**A.C. Generators with Revolving Field.**—The same ruling as given above would apply.

**Transformers.**—Here, again, the limits given above for cotton insulation will apply, but for mica insulation a little higher temperature may be allowed, say, 110° C. actual, as a transformer will usually stand greater overloads than rotating machinery, and there is again no fear of the insulation giving trouble through excessive temperature.

"A. G. R.," to whom the second award (5s.) is made, writes:—

If cotton and fibrous insulated windings are subjected continuously to a temperature above 90° C. the insulation becomes charred and mechanically weak, and, although it may still show fairly efficient electrical properties, the slightest mechanical strain causes crumbling of the insulation, and hence increased possibility of breakdown. Mica, on the other hand, will stand a temperature of 120° C. without the slightest sign of deterioration, but at this temperature ageing of the iron circuits is accelerated and the core losses are appreciably increased.

The following table gives the maximum working temperatures for electrical apparatus as fixed by the Standards Committees in various countries. All the temperatures are in degrees Centigrade.

Description.	British.		Ameri- can.		German.			
					Cotton.		Paper.	Mica.
	$T_T$	$T_R$	$T_T$	$T_R$	$T_T$	$T_R$	$T_T$	$T_R$
Windings—Stationary	—	85	75	75	—	95	—	105

Commutators ...	—	—	80	—	—	—	—	95
Collector rings ...	—	—	90	—	85	—	95	—
Transformers ...	75	75	75	75	95	—	105	—
Railway motors—								
1 hr. rating	—	—	—	—	105	105	115	135
Squirrel-cage rotors...	—	—	80	—	85	—	105	—

$T_T$  refers to thermometer readings, and  $T_R$  to temperatures calculated by increase in resistance of conductors. To obtain temperature rises (maximum), the air temperature is taken as 25° C. for British and American, and 35° C. for German standards.

The usual practice in this country is to fix the safe limit for practically all types of insulation as 60° C. for machines and 70° C. for transformers, which figures, assuming an average air temperature of 20° C., give rises of 40° C. and 50° C. respectively. The temperature rises are generally measured by thermometer in the case of machines, and by increase in resistance of the windings in transformers.

[Stated briefly, so far as the charge engineer is concerned, the following actual temperatures may be taken: Cotton insulation 170 to 180° F. (76½ to 82° C.); mica or micanite 200 to 220° F. (93½ to 104½° C.). The lower figure in each case may be taken for generators, and the higher figure for transformers.—Ed. E.E.]

**The Electrical Industry of Japan.**—A Paper on the present state of the electrical industries in Japan by Prof. Kincura is published in the *Journal of the Society of Arts*. Water power, he says, is plentiful and widely distributed. Out of a possible 10 million horsepower only 300,000 is at present included in present schemes, of which about half is in actual operation. Electrical plant is made in Japan to a considerable extent, but a good deal is imported. The author says that more co-operation between foreigners and the Japanese is desirable in the importing businesses. He also encourages the acquisition of patent rights in Japan. The two largest factories of electrical plant are one in connection with the American General Electric Co. and another forming part of a dockyard. There is also an electrical factory adjoining and in connection with a copper mine. In all cases special iron and steel parts are imported. There are a considerable number of factories turning out the smaller pieces of apparatus. Both carbon and metal filament lamps are made in Japan, as well as porcelain insulators, and the manufacture of micanite from mica from Corea and Manchuria is being commenced. The manufacture of electrical instruments is not highly developed, and there is no regular electrical research laboratory in the country. Supply meters are examined by the Teishinsho, a department of communications, and last year the number reached 38,000. Wires and cables are made to an extent which almost excludes importation; dry cells are made on a small scale, as well as the simpler kinds of arc lamp carbons. Most of the public telephone apparatus has been supplied by two firms, one purely Japanese and the other in close connection with the West. Domestic electric light fittings in Japanese taste are rapidly developing. Domestic applications of electricity other than lighting are hardly used at all.

## ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

### REPORTS OF THE INSPECTORS OF MINES

**A** GOOD many references to electrical matters are contained in the reports of the Inspectors of Mines for the different districts for 1913.

#### Scotland.

Mr. W. Walker gives the number of electric coal-cutters in his district as 700 (including 484 disc and 191 bar machines), as compared with 176 compressed-air machines. The electrical cutters have increased by 107, and the compressed-air cutters have decreased by two since the previous year. Four persons were killed and 11 injured by electric shock during the year. All the fatalities were underground. One was due to faulty insulation on an old unarmoured cable, one to an open switch-box being alive in error, one to a defective earthing system, and the other occurred on a 500-volt lighting circuit with unarmoured cable. Of the non-fatal accidents, six were due to failure of insulation of cables, the inspection of which, says the inspector, is sadly neglected at some mines. Two occurred while fuses were being replaced, two were due to carelessness, and one to pure mischief. The remaining two were on the surface, one due to measurements taken on conductors which were not realised to be alive, and the other to an apprentice touching a fuse with another wire to see if it was live. Three cases of prosecution for offences against safety provision as to electricity resulted in fines. With regard to the regulation as to telephones, Mr. Walker reports that this is gradually being complied with, but some difficulty has arisen in getting a supply of the necessary apparatus. 1,160 electric safety lamps are in use in the district, against 286 in the preceding year. These are of the following makes:—Gray-Sussman, 107; C.E.A.G., 895; Float, 19; Oldham, 55; Wolf, 62; Cremer, 10; others, 12. The aggregate h.p. of motors in use in mines in the districts is 119,639 in the 319 electrically equipped mines, of which 93,361 are underground.

#### Northern District.

Mr. J. R. R. Wilson reports the use of 134 electric (56 disc, 31 bar, 44 chain, and 3 percussive) and 530 compressed-air coal-cutters. There were six underground non-fatal electrical accidents in the district, and five on the surface, but no fatalities due to electrical causes. The inspector remarks that, considering that the use of electricity underground has increased during the year from 64,583 to 79,422 h.p., this result cannot be called unsatisfactory. Under the heading of dangerous occurrences, a fire is reported in a motor room, probably due to lighting cables enclosed in wooden casing. Two workmen were charged during the year with contravention of the rules as to electricity and convicted. 6,662 electric safety lamps are reported as being in use in the district. These are of the following makes:—C.E.A.G., 627; Oldham, 137; Gray-Sussman, 5,715; Wolf, 35; various, 148. The aggregate horse-power of motors in the 272 electrically equipped mines in the district is given as 64,837 on the surface and 79,422 underground.

#### Yorkshire and North Midlands.

Mr. T. H. Mostram reports the use of 331 electric (including 146 disc, 83 bar, and 102 chain machines) and 342 compressed-air coal-cutters in his district, compared with 290 and 311 respectively for the preceding year. The accidents due to electricity were 5 fatal, including 6 deaths, and 5 non-fatal underground, and 2 fatal and 4 non-fatal on the surface. One of the surface fatalities was due to accidental contact between a wire rope and an unprotected switch, and the other to a lad taking hold of a live conductor deliberately after being warned. One of the underground fatalities was due to a man who had tripped grasping an unarmoured 440-volt lighting wire and pulling it out of a connector. In another case an unearthed lamp guard became live through abrasion of insulation. A further fatality was due to a faulty switch on a badly earthed coal-cutter. In another case, a man in falling severed an earth wire, and also came in contact with a live lead; and the remaining underground fatality, in which two men were killed, a broken controller finger caused a badly earthed coal-cutter frame to become alive. The non-fatal accidents were due to various causes. Fines were inflicted in two prosecutions of officials under the electrical rules, and there were five convictions of workmen for offences under this heading. 25,004 electric safety-lamps are reported in the district, consisting of the

following makes:—C.E.A.G., 19,358; Oldham, 1,204; Wolf, 241; Tors, 6; Gray-Sussman, 4,091; Perfected, 43; Bristol, 8; Pape, 1; Float, 1; various, 51. The aggregate horse-power of motors in the 320 electrically equipped mines of the district is given as 51,245 underground and 55,954 on the surface.

#### Manchester and Ireland.

Mr. J. Gerrard reports 11 electric coal-cutters in the Lancashire district and 2 in Ireland. Compressed-air machines are much more widely used in Lancashire, where the number is 196, but there are none in Ireland. One non-fatal accident underground and two on the surface are attributed to electricity. Among "dangerous occurrences," a fire at an electrical resistance is reported. Five haulage hands were fined for endangering life by "larking" with a wire attached to a lamp terminal. 1,216 electric safety lamps are reported to be in use in the district, of the following makes:—Gray-Sussman, 13; C.E.A.G., 420; Cremer, 2; Wolf, 4; Tors, 8; Pape, 2; Thomson Rothmell, 4; Oldham, 759; other makes, 4. The aggregate h.p. of motors in Lancashire is given as 7,938 underground and 5,382 on the surface, and in Ireland 24 underground and 5 on the surface. There are 69 electrically equipped mines in the Manchester district and 4 in Ireland.

#### Liverpool and North Wales.

Mr. A. D. Nicholson reports 23 (5 disc, 15 bar, and 3 chain) electric and 158 compressed-air coal-cutters in the district, against 24 and 124 respectively for the preceding year. There were no electrical accidents of any kind. 385 electric lamps, composed of the following makes, are reported to be in use:—Sussman, 166; Meco, 1; Oldham, 26; C.E.A.G., 190; Wolf, 2. The aggregate h.p. of motors in the 62 electrically equipped mines of the district is given as 12,900 underground and 4,495 on the surface.

#### South Wales.

Dr. W. N. Atkinson reports 36 electric (2 disc, 31 bar, and 3 chain) and 79 compressed-air coal-cutters in his district. There was one underground fatality and one on the surface, and four underground and six surface non-fatal accidents, due to electricity. The fatal underground accident was due to faulty earthing of a pump motor. 2,716 electric safety lamps are reported to be in use in the district, including the following makes:—C.E.A.G., 2,452; Gray-Sussman, 148; Oldham, 70; Float, 22; Wolf, 19; Ackroyd and Best, 5. The aggregate h.p. of motors is given as 91,236 underground and 90,581 on the surface in the 294 electrically equipped mines of the district.

#### Midland and Southern District.

Mr. H. Johnstone reports the use of 70 (29 disc, 20 bar, and 21 chain) electric and 105 compressed-air coal-cutters in his district. The accidents due to electrical causes include two fatal and four non-fatal underground, and one non-fatal on the surface. One fatality was due to a cable from which the insulation had become stripped off by the strings by which it was suspended, and the other was due to a misunderstanding, whereby current was switched on while a man was working on some cables. The inspector writes that every one of the non-fatal accidents could have been prevented had proper care been exercised. One mine-owner was convicted and fined for 18 contraventions of the electrical regulations, and one other prosecution resulted in a fine in one out of three charges brought. 680 electric safety lamps are reported to be in use in the district, of the following makes:—Gray-Sussman, 43; C.E.A.G., 295; Oldham, 169; Bristol, 17; Cremer, 1; Float, 4; Salvator, 2; Wolf, 140 others, 9. The aggregate h.p. of motors in the 132 electrically equipped collieries of the district is given as 9,140 on the surface and 35,294 underground.

Summarising some of the above figures, it will be noted that there are in all 1,307 electric coal-cutters in use against 1,587 driven by compressed air. There have been twelve fatal accidents underground and six on the surface, due to electrical causes, and twenty-six underground, and twenty surface non-fatal electrical accidents during the year. 37,823 electric safety lamps are in use, and the horse-power of motors installed aggregates 345,266 underground and 282,827 on the surface. 1,472 collieries are electrically-equipped out of the total of the 3,302 in the United Kingdom.

## AN ELECTRICALLY WORKED COLLIERY

THE Yorkshire Branch of the National Association of Colliery Managers paid a visit recently to the Ledston Colliery of the Micklefield Coal and Lime Co., and a Paper describing the equipment of this and another of the Co.'s pits was read by the Manager, Mr. J. G. Linneker. The great feature of interest in the Ledston Pit is that it is worked entirely by electric power from the 10,000-volt overhead mains of the Yorkshire Electric Power Co. This supply is transformed down to 2,000 volts for most purposes, and to 400 volts for pumping, haulage, and lighting at a sub-station adjacent to the compressor house, wherein is situated the main distributing switchboard.

The winder in the No. 1 shaft is driven by two direct-coupled continuous-current motors, each rated at 400 h.p., and supplied by an Ilgner motor-generator with a 9-ton fly-wheel. A separate motor-driven exciter is employed, and also an automatically-controlled motor-compressor for the brakes. The equipment is on the usual lines, and was supplied by the Lahmeyer Electrical Co. This shaft is 300 yds. deep, and a wind is made in thirty-eight seconds with an energy consumption of 2 kw.-hours. It is hoped to reduce this to 1.5 kw.-hours by the addition of balance ropes. The winder in the upcast shaft is smaller, and is driven by one continuous-current motor through 12 to 1 Citroën gear. The motor-generator in this case has no fly-wheel, but provision is made so that one can be added later if required. Steam plant was used for the sinking operations, but now the whole plant, including winding, air-compressing, haulage, pumps, and fan are run electrically. Temporary electrical pumping plant was, however, used during sinking.

The air-compressors consist of a Robey vertical compressor direct-driven by a 400-h.p. A.E.G. three-phase motor, a Belliss two-stage machine direct-driven by a 360-h.p. Sandycroft two-speed Cascade motor, and an Ingersoll belt-driven compressor, originally put down for the rock drills used for sinking, and now used only during week-ends, &c. The permanent pumps comprise a Mather & Platt turbine pump to deliver 100 gallons per min. against a head of 30 ft., and driven at 2,900 r.p.m. by a 70-h.p. induction motor in No. 1 shaft and a two-stage turbine pump delivering 200 gallons per min. to a height of 180 ft., driven by a 30-h.p. motor at 1,440 r.p.m., in No. 2 shaft. Ventilation is by an 18-ft. Walker fan, rope-driven by a 360-h.p. A.E.G. motor of a special three-phase commutator type, of which the speed can be varied between 260 and 600 r.p.m. by shifting the brushes. Other examples of electric power are in the driving of a rope-way to the screening plant, and the screening plant itself. In all, the motors aggregate 2,875 h.p., and the energy consumption per month is about 200,000 units.

## ELECTRICAL EQUIPMENT AT A SCOTTISH COLLIERY

A PAPER by Mr. A. M. Russell, published in the Transactions of the Mining Institute of Scotland, describes the sinking and equipment of the Blairhall Colliery of the Coltness Iron Co., near Dunfermline. The sinking of two new shafts, nearly 2,000 ft. in depth, was commenced in 1906. A considerable amount of water was met with, and an electrical pumping plant was installed. The first pump-room contains two sets of horizontal high-lift Sulzer-Brown-Boveri electrically-driven, six stage, turbine pumps, capable of delivering 750 gallons per minute against a 700-ft. head, each being driven by a 250-h.p. motor at 1,490 r.p.m. The second pump-room is provided with a horizontal three-throw ram pump, driven by a 100-h.p. motor at 25 r.p.m., and capable of pumping 250 gallons per minute against a head of 700 ft. The same class of pump is used at the lowest pump-house. This runs at 27 r.p.m., and can deliver 300 gallons against a head of 1,350 ft. It is driven by a 165-h.p. motor. In one of the seams an electrically-driven chain creeper is used to raise the empty tubs to a height sufficient to allow of their gravitating to each side of the pit.

In the power-house there are two Willans mixed-pressure turbines, each driving a Brown-Boveri three-phase 500-kw. 550-volt 50-cycle alternator at 3,000 r.p.m. The condenser pumps are electrically driven, and a Rateau steam accumulator capable of dealing with 20,000 lb. of steam per hour and bridging over stops of 60 seconds, deals with the supply of exhaust steam from the winding and fan engines. The remote control switchboard is fitted with a Brown-Boveri automatic regulator for controlling the voltage. The neutral points of

the alternators can be earthed through a resistance. Three-core double-armoured bitumen-insulated cables are led to the shaft through a brick-lined trench roofed with fire-clay covers. Two cables are taken down the shaft, each capable of supplying half the requirements. These cables are sectionalised at each pump-room. Switches are introduced for linking-up the different lengths of cable. The cable is of the solid vulcanised-bitumen three-core double-wire armoured type, and for the suspension of the cables in the shaft, hard-wood cleats 5 ft. long were used at intervals of 150 ft., with intermediate cleats 2 ft. long arranged at distances of 30 ft. between the others. The earthing arrangements for the pit were carefully considered. A solid copper busbar is erected in the power-house, also at each of the pump-rooms, to which all armoured, motor-frames, &c., are carefully bonded. A cast-iron heavy-ribbed earth-plate is attached to the main earth-bar at the power-station; another earth-plate is placed near the shaft-top; and earth-plates are taken from the earth-bars in each pump-chamber and immersed in the sumps, as it was found that, owing to difficulties in connection with the ground at the surface, this was necessary in order to secure an efficient earth.

An overhead line is taken to the river, from which is drawn the water-supply for the boilers and for the cooling-tower. Another overhead line is taken from the power-station to Blairhall Village for the purpose of lighting. The voltage is reduced in the village to 110, at which pressure the lighting is being carried out. The lighting at the village is equally divided across the three phases, and three 15-kilowatt single-phase transformers are to be installed.

## AN ELECTRICAL FIREDAMP DETECTOR

DEMONSTRATIONS have been given recently with a new electrically-worked firedamp detector, designed by Mr. Alfred Williams. The apparatus, which is known as the methanometer, depends on the catalytic rise of temperature of a capsule of porous stone impregnated with "platinum-black" when exposed to an atmosphere containing inflammable gas, and the novelty in the instrument appears to be in the method adopted for observing the very slight temperature rises which occur with the weak mixtures, which it is most important to be able to observe. This is done by two delicate thermo couples, one of which is in contact with the platinum impregnated capsule, and the other with a similar plain capsule. These are connected to a galvanometer which is deflected when there is a difference in temperature between the two couples, and can be graduated to read the percentage of methane direct. An important feature of the apparatus is the arrangement provided to give a slight preliminary heating to both junctions equally, in order to increase the sensitivity of the platinum-black. This is done electrically by a coil supplied from a single battery cell. A report by Prof. Silvanus Thompson shows that a considerable degree of accuracy of calculation is possible provided that the auxiliary heating current is kept constant. The readings are not affected by variations in barometric pressure. Dr. J. Erskine Murray has also reported favourably upon the apparatus.

**The Wharnccliffe Pit Disaster.**—A good deal of evidence has been heard at the sittings of the adjourned inquest during the past month with regard to the explosion at the Wharnccliffe Silkstone Colliery on May 30th. Some of this turned on the possibility of the explosion having originated in a coal-cutter, which, according to some of the evidence, was actually at work at the time. This machine was reported to be in good condition before the accident, but when examined after the explosion a crack was found. It was suggested that if this damage existed before the explosion, sparks from the motor may have fired gas within the case and communicated the flame to outside. Other evidence pointed to the machine not having been properly bolted together.

**Electricity in the Rand Mines.**—A set of tables of statistics regarding the use of electricity on the Witwatersrand has been prepared by the South African Institute of Electrical Engineers, and was presented to the Annual Congress of the South African Association for the Advancement of Science at Kimberley last month. Particulars are given of generating stations aggregating some 220,000 kw., and the way this is utilised in the various groups of mines. The following figures are the aggregate horse-powers of motors installed for various purposes:—underground pumping, 43,210; underground winding, 21,100; surface winding, 70,321; ore treatment and milling, 62,013. Reduction processes, 47,894; air compressors, 30,105.

## THE TANGENT SYSTEM OF MINE SHAFT SIGNALLING

A NEW visible and audible shaft signalling apparatus, for which great simplicity and reliability are claimed, has been introduced by Donovan & Co. (47 Cornwall Street, Birmingham), in view of the new mining regulations which came into force on July 1st, and stipulated that "in connection with every winding engine there shall be provided an appliance which shall automatically indicate in a visible manner to the winding engineman (in addition to the ordinary signal) the nature of the signal until the signal is complied with."

In this system an indicator is fixed in the winding engine house, consisting of a casing containing a number of separate compartments with glazed fronts, having metallic filament lamps and reflector fixed behind each. In front of each lamp there is a metal stencil bearing the number of the signal. Unless a lamp is burning no number is visible, but immediately a lamp lights the number of the signal stands out in bold relief. The lower compartment contains the operating relays, which are actuated by the signals sent by the banksman or onsetters. The relays are actuated by battery current, and when energised they close strong wedge contacts, cutting in the local battery supply to the signal lamps. The relays are mechanically coupled so that any signal will automatically reset any previous signal. There is thus no possibility of having two signals showing simultaneously. The apparatus can be arranged to give all the audible signals on one bell, or, if thought preferable, a distinct bell can be connected to ring from any level. An audible signal is given by bells in the usual manner. The tone of the bell informs the winding engineman as to the level sending the signal, each level having a differently-sounding gong. As a totally distinctive signal, the banksman's signal can be received on a hooter. Furthermore, the apparatus can show visually the level from which the signals are being transmitted, and in this case also the resetting would be entirely automatic, in a similar manner to the actual signals.

Under the new rules it is required that the banksman must be able to signal to the winding engineman, and also to the onsetters, and to receive further signals from the onsetters. The banksman will therefore require two sets of tappers and one set of bells. One set of tappers will contain as many keys as may be necessary to signal to the winding engineman, and the other set as many as there are levels or insets from which winding is done. The number of bells will also equal the number of levels or insets. The onsetters' outfit consists of a set of keys according to requirements, and one bell for receiving signals from the banksman. The signal tappers or keys are mounted together in a cast-iron casing, with all the terminals brought together in a convenient position for connecting. The keys are grouped in a most convenient manner, suggested by experience, No. 1 and No. 2 keys being placed at the bottom, apart from the rest, as they are required for coal-drawing. The iron casing is fitted with an iron roof and projecting sides to guard against accidental depression of the keys. If preferred, independent Morse tappers can be supplied, which can then be grouped up and fitted in positions most suitable for the particular requirements. In either case it is essential that the tapper is clearly marked with the number corresponding to the signal it is used for.

The wiring consists of multicore cable running from the farthest required point to the engine house, having as many conductors as there are signals to be sent and one common return in addition; therefore the standard equipment, as detailed above, requires a two-core cable. Another multicore cable runs from the banksman to the nearest onsetter, having as many cores as there are signalling levels; afterwards the number of cores in this cable decreases by one as the different signal points are reached. Thus, in signalling from the banksman to four onsetters, the cable to the nearest onsetter would have to be four cores, while to the last position only one core would be run.

It is important to note that in this system the number of depressions of the tapper does not affect the visual signal at all. The number of taps are merely in order to give the engineman a double means of checking the signals, because, in this system, the whole of the signal, that is, the number and nature of the signal and the point from which it is sent, appear on the indicator from the first depression of the key. Further depressions of the key simply confirm the number showing on the indicator. It therefore follows that the tangent system checks the signals, and any mistake is at once apparent to the engineman.

## MINING AND METALLURGICAL PATENTS OF JULY

### Mining.

IN specification No. 15,064, of 1913, the Accumulatoren Fabrik A.G. (Berlin) and J. F. Rüsse describe an electric miner's lamp, combined with a gas detector consisting of a small spark-gap fed by an induction coil within the apparatus, working off the same battery as the lamp. When gas is present a "halo" is produced.

An improved apparatus for electrically igniting safety lamps underground is the subject of No. 17,529, of 1913, by V. E. Joyce and Spagnoletti, Ltd. The chief feature is that the handle of the magneto generator cannot be inserted or worked unless the lamp chamber is closed.

No. 4,436/14, of E. Edward, is for a system of signalling for haulage roads, &c., in which the contacts are in gas-tight boxes, and are worked by pull wires which also form the return wires and link together adjacent contact boxes.

### Metallurgical.

Amongst the specifications published last month were several of interest to electro-metallurgists. No less than six of these related to electric furnaces. In specification No. 13,250/13, I. MOSCICKI, of Lemberg, describes a furnace with a rotary flame, suitable for the treatment of gases and vapours. Circular, concentric electrodes are used, one or both of which must be shaped like a truncated cone. The arc, which is alternating, is formed in a strong magnetic field, which is so arranged as to cause a rapid elongation of the flame during each alternation of the current. Owing to the conical shape of the electrodes, a lower tension can be used for maintaining the arc. Specification No. 24,850/13, by I. RENNERFELT, of Stockholm, relates to arc furnaces which are arranged to oscillate bodily about a horizontal axis in order to agitate the charge. Two sets of electrodes are provided, one at each end of the furnace, and each set consists of a vertical electrode and two horizontal or nearly horizontal electrodes projecting into the furnace from opposite sides. Twophase current is preferable, but other supply systems may be used. The same patentee also describes in specification 226/14 a furnace for the simultaneous melting of different metals in which several crucibles are arranged on the floor of the furnace and heated by centrally-located arcs, the floor of the furnace being meanwhile rotated bodily. An induction furnace, particularly adapted to the conversion of cast-iron into steel, forms the subject of specification No. 3,291/14. The patentee is P. LESCURE, of Dombrowa, and the invention consists in arranging the metal to be treated in a spiral cavity in the furnace, so that the metal itself forms the secondary of a transformer, the primary of which is situated on another limb of the transformer, outside the furnace. Provision is made for obtaining a good circulation of metal round the spiral. A furnace for fusing ferro-alloys forms the subject of specification No. 3,835/14, by the SOC. ELECTRO-METALLURGIQUE DE ST. BERON, of Lyons. It comprises a fusion chamber, in which the two main electrodes of like polarity operate. The fore-hearth is provided with another electrode of opposite polarity. Mechanism is provided to force one of the main electrodes further into the fusion chamber, so as to cause the molten metal to flow out. The other main electrode is then raised to allow a fresh charge to be introduced into the furnace, so that no interruption of the heating is necessary. In No. 6,731, of 1914, FRIED. KRUPP A.G. describes an improved method of water-cooling furnace electrodes. A method of producing a composite billet consisting of a layer of iron or steel coated on both sides with a film or layer of nickel-copper alloy, is described by the B.T.-H. Co., to whom it was communicated by the G.E. Co. of America, in specification No. 19,021/13. The union between the nickel-copper alloy and the steel is effected by interposing a thin sheet of copper between the metals, and raising the temperature to the melting-point of copper in an electric vacuum furnace, having carbon electrodes. The resulting composite billet can be rolled into sheets and used for a variety of purposes. In specification No. 10,980/14, E. A. ASHCROFT, of London, gives particulars of an improved process for the electrolytic manufacture of alkali metals. The improvement consists in the employment of an electrolyte consisting of an alkali hydroxide and an alkali cyanide with or without the addition of other salts. A machine for the production of lap-welded tubing from a thin strip of sheet-metal is the subject of specification No. 8,595/14, by the A.E.G. Co., of Berlin. Two specifications, viz., Nos. 25,393/13 and 743/14, relate to electroplating. The former is by S. COWPER-COLES, and describes an improved method of depositing a coating of

copper upon iron or steel (see *ELECTRICAL ENGINEERING*, July 9th, p. 397), whilst the latter gives particulars of an electroplating machine, having a rotatable container, which forms the cathode of the circuit, whilst the carrier for the articles to be plated is arranged so that very little plating occurs on the carrier itself.

### EXPLOSION-PROOF CIRCUIT-BREAKERS WITH INSTRUMENTS

**I**N a new range of explosion-proof circuit-breakers recently introduced by the General Electric Co. (67 Queen Victoria Street, London, E.C.), provision is made for the attachment of an explosion-proof pedestal-type ammeter. The instrument is provided with long, well-machined flanges to give the metal-to-metal joints similar to those between the circuit-breaker lid and box. The covers of these attachments are

EXPLOSION-PROOF CIRCUIT-BREAKER WITH AMMETER ATTACHED.

strongly bolted on, in order to resist the effects of any internal explosion, and the strong plate-glass window has wire-netting embedded in it which, in addition to strengthening the glass, holds the pieces together in the event of breakage. The inclusion of such an attachment in explosion-proof circuit-breakers permits the connections between the ammeter and the circuit-breaker to be neatly arranged, as will be observed in the accompanying illustration.

### AN ELECTRIC WINDING PLANT

**A**N electric winding plant has recently been laid down for the Heworth Coal Co. The depth of the shaft is

ELECTRIC WINDER AT HEWORTH COLLIERY.

900 ft., and the capacity of the winder is 20 cwt. of coal per wind of two tubs. The average winding speed is 600 ft. per

min. The winding gear, which is shown in the accompanying illustration, was constructed by M. B. Wild & Co. (Birmingham), and consists of a drum 6 ft. in diam. and 5 ft. wide, with post-type brakes. Full emergency devices for applying the brakes are fitted with automatic tripping arranged to prevent over-winding. The indicator is of the vertical type, driven by bevel wheels from the drum shaft. The winder is driven through a Reich type insulating coupling by an 80-h.p. 40-cycle 625-volt "Witton" slip-ring motor running at 380 r.p.m. The design of the controller is such that the winder is completely controlled from a single lever, which performs all the functions necessary for starting, stopping, reversing, and speed regulation. Movement of the lever from the "off" position first closes the oil-immersed stator or line switches. A further movement introduces a liquid resistance into the rotor circuit until the "full on" position is reached. All the parts are mechanically interlocked, so that it is impossible for them to operate in any but the correct order. The backward motion of the lever reverses the sequence of operations. In order to dissipate the heat generated in the liquid resistance during starting up, a special cooling system has been adopted. The General Electric Co., Ltd. (67 Queen Victoria Street, London, E.C.), were the contractors for the switchgear and motors for this installation.

### THE C.M.B. SYSTEM OF ELECTRIC WINDING

**A** RECENT pamphlet issued by Crompton & Co., Ltd. (Chelmsford), on main winding machines gives some notes on their "C.M.B." patent system of control, which employs a continuous-current main winding motor in combination with a special motor-generator. The latter is so wound that the maximum demand from the mains is automatically limited, and the speed can be economically controlled from zero to full value without the use of series resistances. This feature is of particular value for running for extended periods at the slow speed necessary for shaft inspection. Full advantage can also be taken of regenerative braking. During acceleration the voltage on the winding motor gradually rises, but the current remains practically constant at its full-load value, owing to the action of the special windings on the motor-generator, independently of the rapidity of movement of the control lever. The effect of exceeding the normal load of the cage is to increase the time of the wind, but not to increase the kilowatt input.

The motor has special windings for producing a heavy torque during the starting period, and the action of bringing the controller to the "off" position converts the motor into a powerful generator, thus giving all the braking effect required to bring the drum to rest.

The controller is mechanically connected to the depth indicator, and is automatically brought to the "off" position should the driver neglect to switch off at the correct moment. Should the supply fail, or any contingency arise which might cause an overwind, provision is made for automatically tripping the circuit-breaker, which cuts off the supply and causes the brakes to be applied.

This electric braking system, besides having the advantages of economy in causing power to be returned to the mains, is much less productive of shock and wear to the gearing and other parts of the machinery than mechanical brakes, which in this system need only be applied for holding the drum at rest. The usual other safety devices are provided in connection with the depth indicator.

The alternating-current side of the rotary-converter is provided with windings permanently connected to its commutator, and is fitted with amortisseurs which pull the machine into synchronism. The set is started up by means of a plain three-pole switch, no skill being required by the operator as in the case of converters which have to be synchronised before switching on to the mains. The shunt fields of the converter are wound to give unity power-factor, a series field winding also being provided for the purpose of keeping the power-factor constant at the varying loads. The variable voltage generator which is connected in series with the rotary armature, and is excited so as to oppose or assist its voltage, is provided with limit windings previously referred to, these windings being in opposition to the shunt fields. With this arrangement the resultant field of the variable-voltage machine bears a relation to the current supplied to the main motor. The voltage of the generator is varied by altering its excitation, complete control of the main motor being obtained by this method. The main driving motor is provided with a double shunt field winding for the purpose of giving the heavy torque which is necessary at starting,

and the regenerative braking required in order to bring the drum to rest. Complete control is effected by means of two levers of the railway signal type fixed on the driver's platform. The system is already in use in several collieries in Scotland, Yorkshire, and Durham, and in a Shropshire lead mine.

**EMERGENCY GOVERNMENT SERVICE**

THE following letter has been addressed to the Secretary by a member of the Institution of Electrical Engineers:—

Having regard to the extent and importance of military and naval services involving electrical and mechanical engineering, and to the present state of public affairs, I suggest that the I.E.E. should open a register of members able and willing to take temporary Government service, and put that register at the disposal of the Government. I enclose a suggested draft of the statement of particulars which should be on the register:—

TEMPORARY GOVERNMENT SERVICE.—MECHANICAL AND ELECTRICAL ENGINEERS.

*Offer, with Personal and Professional Particulars.*

I, ....., am able and willing to entertain proposals for temporary service under H.M.'s Government in services involving engineering duties.

(Signed) .....

Name in full .....	Postal address .....
Age .....	Notice required .....
Single or married .....	No. of dependent children .....
Health .....	Physical defects .....
Occupation .....	Employer .....
Professional status .....	Practical experience .....
Military, Naval, or Marine experience and status .....	Experience in control of men .....
Languages .....	Services offered for .....
	Specially qualified for .....

**CORRESPONDENCE**

**ELECTRIC VEHICLES.**

*To the Editor of ELECTRICAL ENGINEERING.*

SIR,—I have received a letter from the Secretary of the Electric Vehicle Association of America stating that the Association will be glad to welcome to their annual Convention in Philadelphia, which is being held on Monday, Tuesday, and Wednesday, the 19th, 20th, and 21st October, 1914, any electrical engineers in England who are interested in the electric vehicle and who propose being in the States at that time. I may say that the Electric Vehicle Committee is being represented by its Chairman, Mr. R. A. Chattock, the City Electrical Engineer of Birmingham. I should be glad to be advised of any engineers who are proposing to attend in order that I may notify the Secretary of the Association.

Yours faithfully,

F. AYTON,

*Hon. Secretary.*

Ipswich, Aug. 4th, 1914.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published July 30th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad

15,199/13. **Electric Propulsion of Ships.** B.T.-H. Co. (*G.E. Co., U.S.A.*). In the system described, the propeller is driven by a motor of the Boucherot type with a short-circuited secondary winding so arranged that the secondary circuit will have a relatively high resistance when the secondary current has a high frequency, and a lower resistance when the secondary current has a low frequency. A considerable over-excitation of the alternator is used to provide for increasing the motor torque for reversing and manoeuvring. Two figures.

15,297/13. **Preparation of Tungsten for Lamp Filaments.** F. SIMPSON. In this process of preparing squirted filaments or bars for wire-drawing, the filaments or bars are dried in air, heated in dry hydrogen, re-oxidised by heating to a temperature not above 240° C. in air, and then raised to a high temperature in the absence of oxidising conditions, to bring about reaction between the oxygen and carbon in the substance, and further to cause sintering of the filaments or bars.

16,015/13. **Combined Lighting Dynamo and Starting Motor for Automobiles.** H. LUCAS and H. E. MOORE. This machine can act as a self-regulating dynamo or as a series motor. The shunt regulating winding, when it is employed as a generator, is connected between one of the main brushes and an intermediate brush, but can be put in series with the armature and battery, cutting out the other circuits when the machine is to be used as a starting motor. Four figures.

16,132/13. **Meter Switch Control.** A. PETERSEN and KEMP & LAURITZEN. A system for controlling two-rate meter change over switches or other apparatus on supply circuits by a superposed E.M.F. acting on resonance relays of a type in which the resonance is mechanical. One figure.

2,409/14. **Single-phase Motors.** SIEMENS-SCHUCKERTWERKE. Polyphase commutator motors of the type in which the rotor windings are connected to displaceable pairs of commutator brushes, and the speed is varied by reducing the inclination of the chord joining the brush position of any pair relatively to the axis of the stator winding, and then increasing it in the opposite direction as the brushes pass the position corresponding to synchronous speed. Four figures.

3,594/14. **Current Collectors for Railways.** A.E.G. A double pantograph collector in which the two contact bars are each supported on a parallelogram pivotted frame. These are so interconnected that they have common lower arms and common fixed pivots. One figure.

6,104/14. **Arc Lamp Carbons.** H. AYRTON. Cored carbons with a layer of copper round the core.

7,938/14. **Emergency Lighting.** R. DESPESAILLES. The installation is arranged with an auxiliary circuit fed by an auxiliary source of supply, which automatically comes into action on failure of the main supply. Arrangements are further provided so that, on failure of either circuit, the other can be fed from either source of supply by automatic change-over switches. Four figures.

10,004/14. **Central Station Protective Apparatus.** P. TORCHIO and H. R. WOODROW. A system of bus-bar protection in which bar coupling inductances are provided to limit fault currents, while at the same time drop in voltage is prevented by causing the fault current passing through the protective reactance to induce a voltage in series with the bus-bar voltage. One figure.

11,937/14. **Heating Apparatus.** A. F. BERRY. This specification covers improvements in construction of electric heaters of a kind in which the elements are enclosed in metal in direct contact with radiating fires. Twelve figures.

## Specifications Published To-Day

The following Patent Specifications will be published to day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** LEWIS [Electrode manufacture] 22,222/13.

**Dynamos, Motors and Transformers:** ATELIERS DE CONSTRUCTIONS ELECT. DE CHARLEROI, SOC. ANON. [Starting arrangements] 15,875/13; SIEMENS SCHUCKERT, GES. [Control of A.C. motors] 17,589/13; FULLER [Magnetic motor] 23,277/13; LEECH [Brush gear] 23,867/13; HOLLISTER [Generator regulation] 27,354/13; THOMPSON (*Goldschmidt*) [Frequency transformers] 3,252/14.

**Electrometallurgy and Electrochemistry:** SIEMENS & HALSKE AKT. GES. and HUTH [Manganese-peroxide anodes] 27,365/13; THUM [Electrolytic apparatus] 9,232/14.

**Heating and Cooking:** CLARKE [Heaters and cookers] 17,453/13; VON HENTZEL [Heaters for liquids] 373/14.

**Instruments and Meters:** C. LORENTZ AKT. GES. [Supporting stretched threads] 16,380/13; PAUL [Magnetic balances] 28,950/13.

**Switchgear, Fuses and Fittings:** WILDEY [Snap-action switch] 24,899/13; INGRANIC ELECTRIC CO. (*Cutler Hammer Mfg. Co.*) [Switches] 5,649/14; ROLPH [Switches] 9,492/14.

**Telephony and Telegraphy:** HOWGRAVE-GRAHAM [Constant speed device] 16,198/13; SIEMENS & HALSKE AKT. GES. [Automatic and semi-automatic telephony] 16,538/13; WESTERN ELECT. CO. (*Woodward*) [Code-signalling systems] 25,774/13; [Telephone systems] 2,075/14; [Automatic telephone switches] 2,693/14; GRAHAM [Telephony] 27,679/13; DWYER [Wireless oscillator] 5,281/14; A.E.G. [Condensers] 6,418/14.

**Traction:** BOIRAULT [Connections for railway vehicles] 13,820/13; KONYOUNJIAN [Dynamo-electric machines] 23,698/13.

**Miscellaneous:** PARSONS and BALL [Clocks] 15,928/13; RIGAUD [Lamp and fire-damp indicator] 16,257/13; SIGNAL GES. [Submarine signalling] 16,298/13; HODGSON [Lifts] 16,392/13; SIEMENS BROS. & CO. (*Siemens & Halske Akt. Ges.*) [Röntgen-ray apparatus] 18,673/13; DUIVEN [Electric baths] 25,668/13; ADLINGTON [Signalling apparatus] 8,975/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, Cables and Wires, &c.:** WELLS [Remote control] 10,823/14; SOC. ANON. DES ETABLISSEMENTS L. BLERIOT [Control systems] 16,080/14; HALL [Motor-control system] 16,319/14.

**Dynamos, Motors and Transformers:** AKT. GES. BROWN BOVERI ET CIE. [Electrodes for vapour rectifiers] 285/14.

**Ignition:** ROLL [Spark plugs] 14,561/14; BETHENOD [Magnets] 15,487/14.

**Instruments and Meters:** CIE. POUR LA FABRICATION DES COMPTEURS ET MATERIEL D'USINES A GAZ [Ampere-hour meters for A.C.] 10,707/14.

**Switchgear, Fuses and Fittings:** SOC. ANON. DES AUTOMOBILES ET CYCLES PUGEOT [Safety apparatus] 14,638/14.

**Telephony and Telegraphy:** HULIMANN [Selector switches] 16,234/14; ERFORSCHUNG DES ERDINNERN GES. [Earth signalling] 16,659/14; [Exciting a Marconi antenna] 16,660/14.

The following Amended Specification may now be obtained:—  
F. TOUNSON [Earthing clip] 1,862/13.

## Opposition to Grant of Patents

11,177/13. E. R. CORWIN. **Telephone Systems.** The grant of this patent, which covers an auto-manual system of working for extensions and exchanges, is opposed.

129/14. A. WILLIAMS and L. D. WILLIAMS. **Gas Detecting Apparatus.** Opposition has been entered to the grant of this patent. The instrument utilises a catalytic body, which is heated electrically to increase its sensibility. The further rise in temperature indicating the presence of inflammable gas is detected by thermo-electric means. (This apparatus is referred to under the name of the methanometer on another page of this issue.)

## Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

14,368/00. C. DE KANDÓ. **Control of Liquid Rheostats.** The patent covers improvements in the control of liquid rheostats such as are used for the rotor circuits of three-phase motors or locomotives. The height of the liquid is controlled by compressed air, and pneumatically actuated short-circuiting switch is also used. The valves controlling these are arranged so that the rheostat and short-circuiting switch are pneumatically interlocked.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** F. W. GORE [Clutch arc lamp mechanism] 8,512/03.

**Electrochemistry and Electrometallurgy:** G. W. JOHNSON [Electrolytic preparation of dyes] 7,835/05.

**Ignition:** R. S. LOVELACE [Sparking plugs] 8,474/03.

**Batteries:** J. T. SZEK [Primary battery negative electrode] 8,660/07.

**Switchgear, Fuses and Fittings:** H. ROSE [Quick make and break switches] 8,692/09.

**Telephony and Telegraphy:** W. FAIRWEATHER [Selective signalling apparatus] 9,063/06; A. KORN [Transmission of pictures] 8,727/07.

**Traction:** E. GIRAUD [Safety device for short-circuiting line in event of breakage of conductors] 29,063-4/04.

**Miscellaneous:** C. J. FOX and R. PEARSON [Fire alarms] 8,000/05; H. E. SHEVARD [Motor-car headlamps] 25,634/09.

## A THERMAL TIME LIMIT CIRCUIT BREAKER

A NEW pattern of thermal time element circuit-breaker designed to take the place of the double pole switch and fuse for the control of small motors, &c., has been introduced by Morris & Lister, Ltd. This possesses the advantages of the time element circuit-breaker over the ordinary fuse or combined switch-fuse, while not only is it more compact, but is placed on the market at a figure which renders its substitution for the switch and fuse possible from the cost point of view. It is controlled by thermal strips of a similar nature to those used in the firm's larger type of circuit-breaker, but these are arranged somewhat differently, and are applied in conjunction with an ingenious toggle movement. The mechanism can be seen in Fig. 1, and a front elevation is shown in Fig. 2. Beneath each of the arms constituting the poles a thermal strip (A) is fixed, which is attached at each end to a brass standard. The front standard for each strip forms the contact block for the corresponding pole. These two strips act in conjunction with one another on two pins (B) placed between the strips at right angles to the length of the latter. The two pins, which are hinged together at their centre, are acted upon by the middle points of the strips, so that they are always under compression, and

FIG. 1.—SECTIONAL ELEVATION OF CIRCUIT-BREAKER.

are thus tending to occupy one of two possible positions of the hinge. The one of these positions corresponds to the "in" position of the circuit-breaker, the other to the "out" position. The central hinge of the two pins is made up of a short insulating rod piece (C), with a small notched iron pin (D) attached at right angles near its lower extremity. In the notch of this pin, a push-in piece (E) directly controlled by the handle acts. This push-in piece is fixed parallel to the handle itself, and turns with the handle about the main axis of the breaker. When the breaker is thrown in, the push-in piece acts through the medium of the notched pin (D) and throws the circuit-breaker arms carrying the contact pieces and carbon brushes forward. The circuit-breaker arm is provided at its lower extremity with a small cam (F) forming an extension of the push-in piece, and sliding over a roller (G) forming a click, which is controlled by a fairly strong spring (H). This roller locks the cam, and with it the push-in piece and the circuit-breaker arm, in the "in" position. The effect of its action is to render the operation of the breaker almost equivalent to a quick-make, that is to say, the cam is so shaped that when the breaker arm has passed a certain point of its forward movement, the spring controlling the roller acts through the medium of the cam and tends to force the arm forward into the "in" position. This ensures that the breaker in all circumstances beds well home on the contacts in the "in" position. The cylinder (K) is a rubber buffer, which is depressed by the rear portion of

the breaker arm on coming out, and so releases the handle also.

When an overload of sufficient duration occurs, the strips expand and permit the hinged rods to spring over under the action of the spring into the second or "out" position, which operation disengages the slotted pin from the push-in piece, and so causes the circuit-breaker arm to fly out under the action of its own controlling spring. When the circuit-

FIG. 2.—FRONT ELEVATION WITH COVER OFF.

breaker arm reaches the "off" position it depresses the roller (K), and so disengages it from the cam, whereby the handle is also brought into the "off" position. The breaker is of the loose handle type, and cannot be held in if the overload is still existent. The tension of the spring controlling the hinged pieces can be adjusted, and the rating of the breaker can thus be varied. The usual adjustment is from 75 to 125 per cent. of the normal load. The contacts of the breaker are formed by the above-mentioned brass blocks which in the "in" position of the breaker rest on carefully designed lay-on copper brushes. Substantial carbon breaks are provided.

## ELECTRIC TRACTION NOTES

The new automatic signalling of the Central London Railway, which is now complete, is described in a recent article in the *Railway Gazette*. The track circuit current in this system is alternating, and special impedance bonds, which allow the passage of the continuous power current, but not of the signalling current, are used at every section insulator. Each bond consists of a number of turns of heavy copper bar on a laminated iron core in a cast-iron case placed between the rails. Two of these coils in series, so far as the power current is concerned, but wound in opposite directions, are used. The transformers supplying the signalling current have resistances in series with them, variable resistances controlled by thermo-regulators which keep the current approximately constant as the train passes along the section. The signals on the main portion of the line have no moving parts, but are simply groups of coloured lamps controlled by the relays. The red lamps are run from a circuit of lower voltage than the green, and only one contact is used, that in the latter circuit. The red lamp is in circuit continuously, but is suppressed by the green when it is illuminated by the interaction of the two secondaries on the transformer from which both are supplied. A few electro-pneumatic arm signals are used in the Wood Lane yard. Automatic train-stops, also pneumatically actuated, are used at all stop signals. There are in all forty-seven automatic signals, fifty-three semi-automatic signals, thirteen repeaters, and eighty train-stops. Electro-pneumatic point control is in use at Liverpool Street,

but at the emergency crossings. &c., at other parts of the line, the mechanical frames have been retained, but are interlocked with automatic signals by circuit-breakers on the levers. The work was carried out by the McKenzie, Holland & Westinghouse Power Signal Co., under the supervision of the Central London Railway Co.'s Engineer, Mr. A. R. Cooper.

Iron is now used for axles in lieu of steel on the Burnley Corporation Tramways, and so far is giving good results.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The Channel and North Sea telephone cables are reserved for Government service. The Government has also assumed control of the wireless telegraph service. The use of wireless telegraphy on ships in the territorial waters of the United Kingdom is forbidden, and all vessels entering port are required to dismantle their aerials. All experimental wireless stations are to be closed, but the order does not apply to stations doing public business, such as coast stations which carry on communication with ships at sea.—The London Wireless Society has offered the Government the services of 100 of its members who are ready to act on ships.

Notices and advices with regard to interruptions of telegraph traffic have been so numerous this week that it has almost been impossible to keep track of them. It may, however, be generally accepted that telegrams between Great Britain and the Continent must be written in plain language without abbreviations whatsoever, and the wording must not be in any way curtailed in a manner which would make the meaning dubious. Messages are only accepted at senders' risk, and are subject to censorship and delay. Telegrams between Great Britain and Russia may only be written in plain Russian, French, English, or German. All telegraphic relations between Hungary and Russia, needless to say, were terminated on August 2nd. On the 3rd inst. the Dutch Government suspended the use of secret language for telegrams. On the 4th inst. code language telegrams were not admitted in Turkey. The Government of South Africa only admit tele-

grams in plain English, French, or Dutch, and they must be signed. Abbreviated addresses are not admitted, and radio as well as ordinary telegrams can only be accepted at senders' risk, and are subject to delay and censorship. Private telegrams destined to Switzerland must be written in plain German, French, or Italian, and those without text or signature are not admitted.

The Shanghai-Nagasaki cable and the Vladivostock-Nagasaki cables failed on July 29th, and telegrams for Japan were sent via Formosa at senders' risk. The La Reunion-Mauritius cable was repaired on July 29th, and the Trieste-Corfu cable was interrupted. The Shanghai-Nagasaki cable was working again on the 29th inst. For Bosnia and Herzegovina, telegrams in plain English, French, German, and Italian can be accepted, but no use can be made of commercial marks or signs, and they cannot be accepted without text. Private telegrams to Hungary, or passing Hungary in transit, can only be accepted at senders' risk. The same restrictions apply to telegrams to Greece, Russia, and Turkey. On July 31st telegrams in plain language for Vera Cruz were again permitted in any language, but subject to senders' risk. Telegrams for the Far East, Straits Settlements, and India can only be accepted via Eastern. On the 1st inst. the Indo-European lines between Emden and Berlin were down. The land line between San Domingo and Puerto Plata was interrupted on the 2nd inst., and traffic to and from San Domingo, Curaçao, and Venezuela are subject to great delay. Messages are being sent by boat to Puerto Rico. The Cape Saint Jacques-Doson cable was restarted on this date.

In the House of Commons last week Major Archer-Shee asked the Postmaster-General why no technical expert had been appointed on the Committee to examine into the organisation of the telegraph service (*ELECTRICAL ENGINEERING*, July 23rd, p. 421), and suggested that an engineer of repute and practical experience in telegraph work should be added to the Committee. The reply was that this Committee is concerned more particularly with the commercial aspects of the telegraph service, and that in the circumstances the Postmaster-General does not think it necessary to appoint a technical expert as one of its members. A separate Committee mainly composed of technical experts is at present considering the question of high-speed telegraphy, the principal technical problem of the telegraph service.

## "ELECTRICAL ENGINEERING" TRADE SECTION

— Notes on Tenders Invited and Prospective Business appear on p. 450. —

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**POCKET LAMPS.**—Messrs. Drake & Gorham, Ltd., have issued a very full list of pocket battery lamps in all sizes and prices from 18s. per doz. (complete with case, battery, and lamp) upwards. The great utility and popularity of these pocket lamps and torches since the metal filament lamp has made it possible to utilise very small batteries with comparatively long life, has resulted in an enormous number of sizes and patterns being available and the list in question offers a wide selection.

**CARBON LAMPS.**—A new price list of B.T.H.-Edison carbon lamps has been issued by the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), in which some interesting results of tests are given.

**LUMINOUS BELL INDICATOR SYSTEM.**—A well-thought-out luminous bell indicator system for hotels, &c., is described in a pamphlet from the Sterling Telephone and Electric Co., Ltd. (210-212 Tottenham Court Road). Each room is provided with three pushes, which control coloured lamps over the door of the room and at suitable service points, and these can only be extinguished at the actual door by the servant attending to the call.

**KETTLES.**—A full range of about forty different designs of electric kettles is listed in an illustrated leaflet from the British Prometheus Co., Ltd. (Salop Street Works, Birmingham).

**SUCTION CLEANER.**—A leaflet from the Electrical Engineering and Equipment Co., Ltd. (109-111 New Oxford Street, London) describes the "Bee" electrically driven suction cleaner, which is intended for the use of householders who have an electric supply. By the use of extra attachments, it may be employed for a variety of purposes.

**ENAMELLED WIRE.**—A leaflet from the Sterling Telephone and Electric Co., Ltd., deals with enamelled wire multiple cables for various intercommunication telephone systems.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**GAS PRODUCER PLANT.**—The Power Gas Corporation, Ltd. (Stockton-on-Tees), have just issued two different illustrated pamphlets of different sizes describing their Mond gas-producer plants with and without ammonia recovery apparatus, and their suction and suction-pressure types of plants for power and heating.

**HEATING AND COOKING APPARATUS.**—Some attractive new designs of kettles, hot-water cans, coffee machines, hot-plates, and other pieces of electric heating and cooking apparatus are illustrated in a new leaflet from Krupka and Jacoby, Ltd. (59 Victoria Street, S.W.).

**MOTOR CONTROL.**—The push-button system of motor control of the Igranic Electric Co., Ltd. (147 Queen Victoria Street), is described in a booklet entitled "The Compulsion of Utility."

**THE UNION QUARTERLY.**—The first issue of this new Journal of the Union Electric Co., Ltd. (Park Street, South-west), contains an article on the works where the company's dynamos and motors are made, and descriptions of novelties and other matters of engineering interest.

**ALUMINIUM.**—A leaflet from the British Aluminium Co., Ltd. (109 Queen Victoria Street, E.C.), contains a reprint of an article on an overhead aluminium network feeder by Mr. E. P. Austin, which appeared recently in *ELECTRICAL ENGINEERING*.

**DRILLS.**—A catalogue from E. Duisberg (28 Victoria Street, S.W.) describes the latest patterns of twist drills made by Günther & Co.

### THE NEW EDISWAN SHOW-ROOMS

THE EDISON & SWAN UNITED ELECTRIC LIGHT Co., LTD., have selected an admirable situation for their new City showrooms, at 123-125 Queen Victoria Street, E.C., and the showrooms themselves are in every respect just what showrooms should be. The fine frontage in Queen Victoria Street and the good window display will attract the attention of the thousands who must pass along this thoroughfare each day, and there is the additional practical advantage of an entrance to the trade counter in Upper Thames Street. Our illustration gives but an imperfect idea of the depth of the main showroom, owing to difficulties in photographing, but it indicates generally the large variety of fine fittings displayed there.

A practical feature is the method employed for hanging the fittings, and for switching them on and off. Long white enamelled tubes hang down from the ceiling and terminate in hooks, from which the fittings are suspended, and above each is a tumbler switch with a very long "dolly," or handle. To switch on any fitting, therefore, it is not necessary (as it is in many showrooms) to go to the wall and find, with some

which should be better known than it is, as it should save much wiring in the case of small houses in which economy of wiring is a consideration. In the showrooms there is also a good display of heating and cooking apparatus, electric irons, &c.

A room is set aside for demonstrating different systems of lighting and the effect of different sorts of fittings and lamps—direct, semi-indirect, indirect, Linolite and cornice lighting, colour-matching lamps, &c. Above the showrooms are roomy and convenient offices.

### A TRAIN LIGHTING EQUIPMENT

AN interesting feature of the large exhibit which is being made by Vickers, Ltd., at the Anglo-American Exhibition at Shepherd's Bush, and contains some fine ship models, guns, and examples of miscellaneous tools and metalwork, is the fact that the stand is lighted by a Vickers train-lighting equipment. The apparatus consists of a dynamo, a dynamo regulator, a lamp regulator, and a battery, together with the necessary wiring and lamps. The system is a single battery

difficulty, the switch that controls the particular fitting; the switch is simply pulled on by means of a long rod with a hook at its end. This arrangement allows every fitting to be lighted without the slightest difficulty or complication, and should save much time both to the seller and purchaser.

Justice cannot be done to the artistic designs of the fittings by a mere description; we were particularly struck with the refined taste shown in the design of the comparatively inexpensive, as well as in the more costly examples, with the remarkable result that, in spite of the multiplicity of styles and "periods," the combined effect of the mass of diverse specimens was not jarring, as it might reasonably be expected. Among the smaller fittings we noticed many neat and elegant single-light pendants and table standards, and the number of beautiful shades for the latter showed that every detail had received its due attention. Of the smaller fittings we noted a pleasing design of convertible table and bracket standard, which is the Admiralty registered design for ship-work, but should also be quite effective for dining-room and drawing-room use ashore.

In addition to actual fittings, the best and newest patterns of accessories are also exhibited, including the Ediswan interlocking fool-proof switch plugs for domestic use, and a practical ceiling rose combined with pull-on and pull-off switch,

one, and operates briefly as follows: The dynamo is of the shunt type, and contains no automatic switches or governors. It is carried below the coach and driven by a belt in the usual way. The brushes are mounted on a moving arm, which is automatically rocked over by the friction of the commutator when the direction of rotation changes, consequent on the direction of motion of the train changing. The dynamo regulator, or the regulator controller, as the makers call it, consists of a field regulator operated by a solenoid which has two coils. The main coil is connected in series with the dynamo, and operates the regulator, and consequently the shunt resistance, in terms of the dynamo output. The auxiliary coil is out of circuit until the battery has become fully charged, when it is cut in by an automatic switch. This auxiliary coil exerts a preponderating pull on the solenoid, as compared with the main coil, and when it is in circuit it inserts such an amount of resistance in the dynamo field that the dynamo output is reduced to a few amperes, and the battery is consequently prevented from being overcharged. The regulator controller also contains a dynamo cut-in and cut-out switch, which closes or opens the circuit to the battery and lamps at a pre-determined voltage. It is operated by a compound-wound electro-magnet, one of the coils of which is connected across the dynamo terminals, and

the other of which is in series with the dynamo. A further feature of the regulator controller consists of an adjustable shunt of low resistance, so arranged that any part of it may be connected in parallel with the main coil of the regulator. The dynamo output may be set to any desired value by passing a greater or less part of it through this shunt. The lamp current is taken from the shunt, and it is possible so to regulate it that any proportion of this current shall pass through the regulator shunt coil. These arrangements allow regulation to be made at will on either total dynamo output or battery charging current, or a combination of both. The dynamo output varies directly with the load, while current is supplied to the battery at its normal charging rate until it is fully charged. There is also a lamp voltage regulator which cuts resistance in or out of the lamp circuit, and so maintains the lamp voltage, approximately constant. As an additional feature of their train-lighting equipment, Vickers, Ltd., have developed a type of electric car heater which can be used in connection with it. Two such heaters are exhibited, one of 1,500 watts, and the other of 500 watts, both suitable for a 24-volt circuit.

### MAZDA MERIDIAN LAMPS

THESE lamps have been specially designed to give a larger proportion of their light downwards than standard Mazda lamps with vertical filaments, without the use of ordinary reflectors. The filament of the Meridian lamp is of drawn tungsten wire, wound in a very close spiral. It is formed in the shape of a star, and is mounted in the horizontal plane (with the lamp hanging vertically), so that nearly all the light is thrown directly downwards. This spiral formation adds considerably to the strength of the drawn-wire filament, and also permits a compact arrangement of the light source, even in the fairly high candle-power lamps, which would not otherwise be possible. The lamp can, if desired, be supplied

**MAZDA**  
B.T.H. PATENT.

MAZDA "MERIDIAN" LAMP FOR  
DOWNWARD ILLUMINATION.

FIG 2.—PLAN OF  
FILAMENT.

with a close-fitting opal reflector attached by a screw fixing ring. These reflectors take up very little more room than the bare lamp, and from that point of view may be considered as a part of the lamp. The Mazda Meridian lamp is regularly made in three sizes, 30, 40, and 60 watts for 100-130 and

200-260 volts. It can also be supplied in 20 and 100 watt sizes for 100-130 volts. These lamps are suitable for use in all conditions where an intense illumination is required over a small area, as in the lighting of desks, machine tools, shop windows, billiard tables, &c., &c. Readers who are interested in this new lamp should apply for further particulars to the British Thomson-Houston Co., Ltd., Mazda House, 77 Upper Thames Street, London, E.C.

### TENDERS INVITED AND PROSPECTIVE BUSINESS

#### Generating Stations, Sub-Stations, Mains, &c.

**Cleckheaton.**—Sanction is to be asked for a loan of £8,085 for extensions to the electricity works.

**Grimsby.**—Mr. W. A. Vignoles, the Borough Electrical Engineer, has presented a scheme for extending the plant at the electricity works at an estimated expenditure of £30,000, including prospective expenditure on mains and services. A special Sub-Committee has been appointed to report upon the matter.

**London: L.C.C.**—High- and low-tension cables and stone-ware ducts for the tramway system. Clerk. September 8th. (See advertisement on another page.)

Supply of electric clocks on a rental basis in London is required by H.M. Office of Works. Tenders by August 12th.

**Newport (Mon.)**—The Electricity and Tramways Committee recommends an expenditure of £16,000 on new cables, &c.

**South Africa.**—The Mossel Bay (Cape Province) Municipality proposes to borrow £11,500 for an electric lighting scheme.

**Sunderland.**—Two 1,500-kw. rotary-converters or motor-generators. General Manager. August 19th.

**Walsall.**—Mains are to be extended to Rushall at a cost of £1,147.

**Wednesbury.**—The Electric Lighting Committee recommends the installation of a 300-kw. rotary-converter and transformer with the necessary switchgear at an estimated cost of £1,086.

#### Wiring

**Brentford.**—The Board of Guardians have decided to wire at an expenditure of £40 two blocks at the infirmary.

**Govan.**—Electric lighting at Hawkhead Asylum. August 8th. Clerk. Govan District Board of Control, 7-8 Carlton Place.

**Edinburgh.**—Electric lighting installation at City Museum. City Electrical Engineer. August 17th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Clacton-on-Sea.**—Elementary school.

**Croydon.**—Ten houses, Kilmartin Avenue, and eight houses. Annandale Road. P. Richardson, 30 Addiscombe Avenue.—Three shops, 316-320 Whitehorse Road. W. B. Coomber. 65 Pemdevon Road.

**Erith.**—Elementary school at Belvedere.

**Finchley.**—Elementary school, Summers Lane.

**Huddersfield.**—Cinematograph theatre. Architects, J. Berry & Sons, 3 Market Place.

**Manchester.**—Cinematograph theatre, Patricroft. Architects, Thornley Bros., Wigan.—Extensions, Withington Hospital. South Manchester Guardians.

**Rochdale.**—Alterations at Town Hall. Architect, P. W. Hathaway, Town Hall.

**Sheffield.**—New Shaftesbury Hotel, West Street. Architect, H. Webster, St. Marie's Chambers, Norfolk Row.

**Swansea.**—Block of offices in Adelaide Street. Mr. R. Borlase Matthews is responsible for the electrical equipment.

**Willesden.**—New police court.

**Worthing.**—Cinematograph theatre, Chappel Street.

**Wrexham.**—New town hall.

#### Miscellaneous

**Australia.**—The Melbourne Corporation requires 1,234 meters. Particulars from McIlwraith, McEacharn & Co., Bilter Square Buildings, E.C. Tenders by August 18th.

**Bradford.**—An expenditure of £21,800 upon extending the tramways to Baildon has been sanctioned.

**Brighton.**—Mr. J. Christie, the Borough Electrical Engineer, recommends the adoption of more modern lighting appliances on the sea front, which he anticipates will give better illumination without increased cost.

**Southport.**—Electric organ-blowing equipment, Christ Church. Archdeacon Madden.

**Swinton & Pendlebury.**—Cables, fittings, &c., for public lighting of three and a half miles of street. Borough Electrical Engineer. August 19th.

### TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Bolton.**—The following tenders have been accepted: Two 1,000-kw. and two 600-kw. rotary-converters, British Westinghouse Co.; E.H.T. three-phase switchgear, British Thomson-Houston Co.; H.T. single-phase switchgear, Johnson & Phillips.

**Leeds.**—The tender of Siemens Brothers Dynamo Works for a turbo-alternator and condensing plant at £34,160 has been accepted, subject to the sanction of the L.G.B. to the necessary loan.

**Salford.**—The tender of the Brush Electrical Engineering Co. has been accepted for twenty-four double-deck bogie cars with vestibule ends; twelve of these cars will have top covers.

**Stoke-on-Trent.**—The Bastian Meter Co. has received a contract for 3- and 5-ampere meters from the Electricity Department.

**Wallasey.**—The tender of the Brush Electrical Engineering Co. has been accepted for the supply of six double-deck cars with top covers, complete with trucks and electrical equipment.

**Walsall.**—The following tenders have been accepted: Turbines, alternators, and auxiliaries, Belliss & Morcom, £17,448; boiler-house plant (four complete boiler units), Babcock & Wilcox, £20,124.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper: Metal Exchange Closed.**—Owing to the closing of the Metal Exchange we are unable to give the usual price of copper this week.

**Reduction in Cable Prices.**—By an unfortunate accident, the error in quoting the price of Henley's 3/22 non-Association Class "W" cable was repeated in our issue of July 23rd. The price is £9 15s. per mile.

**New Zealand Agency.**—An electrical engineer in Wellington (N.Z.) desires to secure the agencies of United Kingdom firms manufacturing dynamos and motors, country-house lighting outfits, switchboards, accumulators, testing instruments, electrical heating apparatus, &c. Further particulars at 73 Basinghall Street, E.C.

**Liquidation.**—A petition for the winding-up of the Leitner Electrical Co., Ltd., will be heard before Mr. Justice Neville in the Chancery Courts on October 13th. Creditors should communicate with Clinton & Co., 59-60 Chancery Lane, W.C.

## SMIT TRANSFORMERS

**RELIABILITY. LOW IRON LOSS.  
CLOSE REGULATION.

CODE—A.B.C., 5th Edition.

**Bankruptcy.**—Trubie Moore, Electrical Engineer, 75 Headingley Mount, Kirkstall Lane, Leeds, has been adjudicated a bankrupt. A first meeting of creditors will be held at the Official Receiver's office, 24 Bond Street, Leeds, on August 7th, at 11.30 a.m., and the public examination will be held at the County Court House, Albion Place, Leeds, on September 8th, at 11 a.m.

**Works Holidays Cancelled.**—The Edison & Swan United Electric Light Co., Ltd., notify us that, owing to important Government business, they have been compelled to abandon the holidays fixed for the present week, and they re-opened on Monday last, August 3rd.

### APPOINTMENTS AND PERSONAL NOTES

At the Whitehall Club on Tuesday, July 28th, Mr. Mark Robinson and Mrs. Robinson were presented with a memento on the occasion of their golden wedding. Some five hundred friends had subscribed to the memento, which was presented in conjunction with an album containing their signatures.

The salary of Mr. W. Marsh, Tramway Manager at Brighton, is to be increased from £400 to £500 per annum.

The Walsall Electricity Committee recommends the appointment of a canvasser in the Electricity Department at a salary of two guineas per week.

A junior draughtsman is required in the Stepney Electricity Department. (See advertisement on another page.)

**Another Fatality at Cardiff.**—We regret to state that a second fatal electrical accident occurred last week in a disconnecting box of the Corporation in Cowbridge Road, when a man named G. H. Rich, who was engaged in fixing a protective covering on a 6,600-volt cable, accidentally cut the insulation of an adjoining 2,400-volt cable and received a shock from which he died.

## LOCAL NOTES

**Brighton: Protest against Relieving Rates.**—At the last meeting of the Corporation, Alderman Gervis, Chairman of the Electricity Committee, protested against the allocation of the profit of £2,342 upon the electricity undertaking last year to the relief of rates. We reported with regard to the Brighton accounts in our issue for July 2nd, page 392, and the Council has already decided to appropriate the balance in the way described. In formally recommending, as Chairman of the Committee, that this decision of the Corporation be carried out, Alderman Gervis said, according to the *Sussex Daily News*, that he was exceedingly sorry the Lighting Committee "had become so infected by the rotten system of finance introduced by the Finance Committee."

**Cardiff: Electricity Accounts.**—The number of units sold last year increased by 656,910 over that of the previous year, whilst the number of consumers increased by no less than 453, making a total of 8,266. The balance in hand now stands at £10,501, and the Borough Electrical Engineer, Mr. Arthur Ellis, recommends that as large a proportion of this as possible shall be carried to depreciation, which in his opinion should equal 10 per cent. of the total capital invested. A recommendation by the Electricity Committee that this amount should be carried to the revenue account of the undertaking was adopted at the last meeting of the Council.

**Edinburgh: Electricity Surplus.**—The Electricity Committee recommends that the surplus on the electricity undertaking for the year, viz., £684, be applied in reduction of capital outlay. This matter is to be discussed later in detail.

**Gloucester: Satisfactory Electricity Progress.**—The past year of the electricity undertaking was one of materially increased progress in all branches. There was also considerable increase in revenue, coupled with a reduction in working expenditure. After meeting all capital charges there was a net profit of £595, compared with a deficit of £106 in the previous twelve months.

**Liverpool: Municipal Engineers as Consultants.**—At the last meeting of the Corporation a protest was raised against Mr. H. Dickinson, the City Electrical Engineer, having received a fee for giving advice to the Salford Electricity Committee. It was pointed out, however, that the Electricity Committee had agreed to the loan of the services of Mr. Dickinson to the Salford Electricity Committee, and that as the latter had chosen to send a fee for these services, it would not be courteous to return it. Furthermore, the standing orders allow for the Liverpool municipal officers to undertake such work with the consent of the Corporation, which consent was obtained in this case.

**London: Lambeth: Price of Electricity.**—Correspondence has taken place between the Council and the South London Electric Supply Corporation with reference to a proposal of the latter to increase the price charged for electrical energy. The Council take exception to this on the ground that the total working costs of the Company are below the average working expenses of the London supply companies, and urges the Company to revert to the original charge for supply. The Directors replied that the increase proposed is unavoidable, and disputed the right of the Borough Council to challenge the right of the Company to fix its own prices. It is understood that further correspondence has ensued, and that the Directors have promised to discuss the question with the representatives of the Council.

**Maidenhead: Electricity Profits.**—The electricity accounts for last year show a net profit of £370, but this is after paying £560 out of revenue for works of a capital nature.

**Southampton: Report on Electricity Undertaking.**—Sir John Snell, President-Elect of the Institution of Electrical Engineers, and Mr. E. Edmonds, a chartered accountant, have presented a joint report upon the general position of the electricity undertaking. There has been a good deal of controversy concerning the commercial policy to be adopted in the management of the electricity undertaking, in which Mr. H. F. Street, the Borough Electrical Engineer, and the Chairman of the Electric Lighting Committee have differed. The report goes into the administration of the Department in considerable detail, and deals with various questions in three sections. It is first stated that the undertaking is perfectly solvent on the basis of its present capitalisation, and the opinion is expressed that the Department can afford to reduce its charge to the Tramway Department. It is regarded as a mistake that the private lighting rates were reduced a short while ago from 3½d. to 3d., and further reductions are regarded as unwise in view of the possible

additional economies in metal-filament lamps. The main point of difference between the Borough Electrical Engineer and the Chairman of the Electric Lighting Committee has been with regard to the charge of ½d. per unit for current for heating purposes. With regard to this the report states that if taken alone, this rate could not be justified, but when its effects on the other departments are considered, then the general improvement in the all-round profits justifies the policy. It is added that in the opinion of the authors of the report, the ½d. per unit policy has not adversely affected the financial soundness of the undertaking. Indeed, the report goes further, and states that if every present lighting consumer took energy for heating and cooking at the ½d. rate to the same extent as the very limited number of consumers who actually purchased in 1912-13, a larger net profit to the undertaking as a whole would result, even at the present high price of coal. At the same time the Council is recommended to consider the adoption of a different type of charge for domestic purposes for either lighting, heating and cooking, or any combination of these three, such, for instance, as a rateable-value system, or upon the basis of a fixed charge per kw. connected, plus ½d. per unit metered. It is only fair, adds the report, to say that the Electrical Engineer has already had in mind a recommendation to this effect. The report also deals with the question of depreciation of meters, cookers, radiators, &c., as well as prepayment installations, and concludes with an expression of opinion that considerable enterprise has been shown in the management and development of the undertaking, and that it will be contrary to the interests of ratepayers and consumers alike were any check to be given to it by a reversal of the main lines of policy. Briefly, the report is a vindication of Mr. Street, who has been the subject of much adverse criticism.

**Southport: Dispute with Contractors.**—The dispute between the Corporation Electricity Department and the local electrical contractors, referred to in our issue of July 2nd, p. 392, was carried a step further last week when another deputation waited upon the Electricity Committee with regard to the matter. The general case, as already stated, was again emphasised to the Committee, but it was decided to defer giving a reply until there had been time for further consideration of the question.

**Warrington: Increased Power Profits.**—The power supply last year showed an increased profit of £3,283, compared with the previous twelve months.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**London Supply Companies' Dividends.**—The following dividends have been declared:—Kensington & Knightsbridge Co., an interim dividend at the rate of 8 per cent. per annum.—City of London Electric Lighting Co., interim dividend of 3 per cent.—Charing Cross, West End & City Co., interim dividend at the rate of 5 per cent. per annum.—County of London Electric Supply Co., interim dividend of 2½ per cent.

## SUMMARY

AN official communication from H.M. Commissioner of Works states that steps are being taken to continue all Government building and engineering work. (Page 453.)

WE publish some details of Germany's electrical export trade, which should be of interest to manufacturers in this country, as they give quantitative particulars of Germany's commercial activity in various countries in each of the different branches of the electrical manufacturing industry. (Page 455.)

WE give some figures of the number of electrical employees with the Army. (Page 455.)

A QUESTION relating to the design of brush-gear appears in our Questions and Answers columns. (Page 456.)

THE subjects of the Patent Specifications published last week include starting A.-C. motors, heating and cooking apparatus, arc lamp carbons, car-lighting dynamos, and wireless telegraph apparatus. (Page 456.)

A NEW method of eliminating the third harmonic from the wave form of three-phase generators has been proposed by Mr. R. J. Jensen, of Copenhagen. (Page 457.)

THE Institution of Electrical Engineers is preparing a register of men willing to undertake national service of an electrical character. (Page 457.)

THE wiremen's dispute has been settled. (Page 457.)

THE Electrical Trades Benevolent Institution is willing to recommend men now out of work to take the place temporarily of those called out in connection with the war. (Page 457.)

A PLEA for larger air-gaps in induction motors was the substance of a paper recently read before the Association of Mining Electrical Engineers. (Page 458.)

NOTES on the arrangements for the next session at some of the Universities and Technical Colleges are given on page 458.

WE are able to give full particulars of the effect of the war on telegraphic communication throughout the world. (Page 458.)

A NEW power station is contemplated at Blackpool; new cable is required at Bolton, Burnley, Clacton, Gillingham, and Turton; a loan of £21,323 has been sanctioned at Aylesbury; the installation of two suction gas engines driving 33 kw. is recommended at Portrush, and a new 500 kw. turbo-alternator is required at Eastbourne.—A loan of £1,500 has been sanctioned for mains at Hereford. (Page 459.)

A CHARGING station for electric vehicles is to be set up at Eastbourne.—The Glasgow Corporation electricity accounts for last year show a net profit of £819 after setting aside £52,171 for depreciation.—A very successful rearrangement of the electric lighting of the Manchester libraries is being carried out.—The Hove municipal electricity undertaking for its first quarter's work shows extremely successful results. (Page 460.)

THE Yorkshire Electric Power Co. records a net profit for the past year of £10,414, against £6,972 in the corresponding period of last year. (Page 460.)

## GOVERNMENT BUILDING AND ENGINEERING WORK TO CONTINUE

WE have received the following official announcement for publication:—

"It appears from various enquiries addressed to the Commissioners of Works that there exists some apprehension lest unemployment should be increased in the building and other trades by suspension during the present crisis of building and engineering operations provided for in the estimates of the Office of Works recently approved by Parliament. It is, therefore, desirable to state publicly at once that it is the intention of the Commissioners of Works to proceed with all services in their charge, to employ as many men as possible to carry out such services, and to develop and expedite their building programme in any way practicable.

"As the Minister mainly responsible for Government building, the First Commissioner of Works would wish to take this opportunity of expressing his sincere hope that private individuals, companies, firms and contractors will spare no effort to follow the policy of the Government in this matter, so far as circumstances admit."

The Postmaster-General has also expressed his intention to take steps to start work on the new Post Office tube railway.

## GERMANY'S £14,500,000 ELECTRICAL EXPORT TRADE ANALYSED

IT is not generally realised to what an enormous extent Germany's exports of electrical machinery and apparatus have been rising during the last two decades. In 1913 the value of these exports had risen to £14,500,000. During the war these exports will be practically nil. In considering the effect of the war on the electrical industry of this country, account must be taken of the markets which are opened to us immediately owing to Germany's inability to supply. We use the word immediately, and we use it advisedly. Trade to the extent of fourteen and a half millions a year will, it is true, not be transferred to us; but we are able to publish some statistics which show that a large proportion of this export trade of Germany can be ours if we take the proper steps to obtain it, and that some of this can be ours at once.

We have been fortunate enough to get access to a German official return giving particulars of the trade of that country in great detail. To the best of our belief, there is only one copy of this return in England at the present moment, and we may regard ourselves particularly fortunate in being able to publish some of its contents for the benefit of our readers at the present juncture. The return contains a list of Germany's chief customers for its export trade under classified headings, and indicates the proportion which each country has been buying from Germany.

It is seen, for instance, from the figures relating to electrical machinery and apparatus given below that in 1913 British South Africa bought over 1,000 tons of generators, motors, and transformers, about the same weight of cable, 29 tons of metal filament lamps, and 14 tons of electrical measuring instruments and meters from Germany. Belgium has, it will be noticed, been an excellent customer of Germany's for electrical goods; is it unreasonable to expect that she will transfer her custom to us after the war? Argentine and other South American countries are good buyers; they already use a great number of British electrical apparatus, and it is to be hoped that their present electrical requirements will to a large extent be supplied by us. The amount of cable exported by Germany has been enormous in recent years, and they sold nearly two million pounds worth abroad in 1913, including far too big a proportion in this country; it is not unreasonable to hope that a very large proportion of this will be transferred to British manufacturers. The magnitude of the figures relating to electric lamps should give joy to our lamp manufacturers, both small and large. They will have in the first place to tax their works to the utmost to make the lamps required in this country alone, large numbers of which, it is seen, have hitherto been imported from Germany.

We have above only given a few examples, but the full figures for the various electrical products and the countries to which they have been exported are added at the end of this article. The publication of these statistics by us will, we hope, encourage all our electrical manufacturers to lose no time in making an attack on Germany's markets abroad. Although the statistics do not give the values of the exports to each country, but only weights, yet the total weights and total values are given for each item, and it is therefore possible to make a very fair estimate of the value of each particular branch of the trade in every country.

To return to the point mentioned already that a useful proportion of this trade may be diverted to us immediately: we have worked out approximately the proportion of the whole of Germany's exports which have gone to Austria, Russia, and France, and deducted them from the total of £14,500,000. The figure thus obtained is £12,300,000, which represents approximately the trade that might be opened to the other countries which are not at

war. It is obvious that, as these other countries have had their supplies of electrical goods from Germany suddenly cut off, they must immediately begin to buy at any rate a certain proportion of them elsewhere, and we have practically to divide the first spoils with Canada, the United States, Switzerland, and Italy, who, with ourselves, are the chief producers of electrical apparatus and machinery able to continue manufacture. It behoves us, therefore, to lose no time and to see that we get as much business as possible to make up for the business lost, and to keep our manufacturing works going so as to avoid distress among the workmen and staffs.

The business momentarily lost by the war is, of course, difficult to estimate, but, so far as the electrical industry is concerned, we believe that more harm will be done through the disorganisation immediately following the outbreak of war, and the difficulty in the financial position, than by the actual loss of trade. Our electrical exports to Germany, Austria, Russia, France, and Belgium during 1913 were only £511,440, representing but one fourteenth part of our total electrical exports. We lose these now, but we should soon replace them by our share of the £12,300,000 from Germany.

### German Exports in 1913.

The total exports of electrical machinery and apparatus from Germany to all countries in 1913 were of a total value of M.290,482,000, say £14,500,000, and the total weight of these was 133,855 metric tons.

#### Generators, Motors, Transformers, and Choking Coils.

*Machines, &c., up to 25 kg. in Weight.*—Total weight, 741 tons. Value, £144,350. Number of articles, 78,039. Chief countries exported to were:—Belgium, 41 tons; France, 59 tons; Great Britain, 58 tons; Italy, 41 tons; Austro-Hungary, 120 tons; Russia, 182 tons; Switzerland, 41 tons; Spain, 34 tons.

*Machines, &c., from 25 to 100 kg. in Weight.*—Total weight, 3,146 tons. Value, £361,000. Number of articles, 57,356. Chief countries exported to were:—Belgium, 198 tons; France, 236 tons; Great Britain, 268 tons; Italy, 147 tons; Holland, 238 tons; Norway, 60 tons; Austro-Hungary, 532 tons; Russia, 505 tons; Switzerland, 106 tons; Spain, 243 tons; Japan, 63 tons; Argentine, 106 tons; Brazil, 101 tons.

*Machines, &c., from 100 to 500 kg. in Weight.*—Total weight, 7,753 tons. Value, £721,200. Number of articles, 36,528. Chief countries exported to were:—Belgium, 641 tons; Denmark, 147 tons; France, 350 tons; Great Britain, 760 tons; Italy, 347 tons; Holland, 533 tons; Norway, 222 tons; Austro-Hungary, 613 tons; Portugal, 76 tons; Roumania, 116 tons; Russia, 809 tons; Finland, 157 tons; Sweden, 142 tons; Switzerland, 108 tons; Spain, 574 tons; British South Africa, 98 tons; Japan, 128 tons; Argentine, 491 tons; Brazil, 532 tons; Chili, 192 tons; Mexico, 110 tons; Australia, 129 tons.

*Machines, &c., over 500 kg. in Weight.*—Total weight, 25,639 tons. Value, £1,599,850. Number of articles, 11,919. Chief countries exported to were:—Belgium, 2,168 tons; Denmark, 267 tons; France, 1,214 tons; Great Britain, 1,228 tons; Italy, 1,613 tons; Holland, 1,150 tons; Norway, 1,270 tons; Austro-Hungary, 842 tons; Portugal, 229 tons; Roumania, 696 tons; Russia, 2,171 tons; Finland, 238 tons; Sweden, 443 tons; Switzerland, 573 tons; Spain, 2,239 tons; British South Africa, 906 tons; India, 547 tons; China, 266 tons; Japan, 2,419 tons; Dutch Indies, 362 tons; Argentine, 1,387 tons; Brazil, 1,144 tons; Chili, 630 tons; Mexico, 457 tons; Peru, 124 tons; Uruguay, 158 tons.

*Separate Armatures and Commutators.*—Total weight, 4,603 tons. Value, £393,750. The chief countries exported to were:—Belgium, 246 tons; France, 223 tons; Great Britain, 328 tons; Italy, 377 tons; Holland, 294 tons; Austria, 597 tons; Russia, 664 tons; British South Africa, 93 tons; Japan, 328 tons.

*Accumulators and Parts.*—Total weight, 6,452 tons. Value, £286,850. The chief countries exported to were:—Denmark, 823 tons; Holland, 892 tons; Norway, 632 tons; Sweden, 878 tons; Switzerland, 211 tons; Japan, 323 tons; Argentine, 622 tons; Brazil, 228 tons; Chili, 531 tons; Austria, 41 tons.

*Cable.*—Total weight, 47,591 tons. Value, £1,963,400. The chief countries exported to were:—Belgium, 5,305 tons; Denmark, 1,025 tons; Great Britain, 1,073 tons; Italy, 522 tons; Holland, 6,955 tons; Norway, 3,565 tons; Austria, 26 tons; Portugal, 240 tons; Roumania, 567 tons; Russia, 159 tons; Finland, 473 tons; Sweden, 2,281 tons; Switzerland, 67 tons; Spain, 720 tons; Turkey, 175 tons; Egypt, 234 tons; British South Africa, 1,195 tons; China, 507 tons; Japan, 3,724 tons;

Chili, 594 tons; Mexico, 301 tons; Uruguay, 516 tons; Australia, 691 tons. In addition, 4,739 tons of submarine cable was exported.

**Arc Lamps and Mercury Vapour Lamps.**—Total weight, 595 tons. Value, £143,000. Number of articles, 51,838. The chief countries exported to were:—France, 18 tons; Great Britain, 74 tons; Italy, 36 tons; Austria, 40 tons; Russia, 138 tons; Argentina, 105 tons; U.S.A., 25 tons.

**Arc Lamp Carbons.**—Total weight, 7,051 tons. Value, £491,300. The chief countries exported to were:—Belgium, 555 tons; France, 387 tons; Great Britain, 1,740 tons; Italy, 619 tons; Holland, 214 tons; Austria, 428 tons; Russia, 243 tons; Switzerland, 107 tons; Dutch Indies, 69 tons; Argentina, 437 tons; Brazil, 83 tons; Canada, 98 tons; U.S.A., 1,312 tons; Australia, 118 tons.

**Spare Cases and Globes, &c., for Arc and Mercury Vapour Lamps.**—Total weight, 85 tons. Value, £21,600. The chief countries exported to were:—France, 9 tons; Great Britain, 6 tons.

**Projectors and Reflectors.**—Total weight, 283 tons. Value, £97,950. The chief countries exported to were:—Great Britain, 25 tons; Austria, 21 tons; Russia, 60 tons; Japan, 48 tons; U.S.A., 2 tons.

**Metal Filament Lamps.**—Total weight, 2,114 tons. Value, £2,251,900. Aggregate number of lamps, 48,264,231. The chief countries exported to were:—Belgium, 107 tons; Denmark, 61 tons; France, 100 tons; Great Britain, 148 tons; Italy, 155 tons; Holland, 34 tons; Norway, 68 tons; Austria, 233 tons; Portugal, 15 tons; Roumania, 16 tons; Russia, 325 tons; Finland, 35 tons; Sweden, 74 tons; Switzerland, 96 tons; Spain, 104 tons; British South Africa, 29 tons; India, 13 tons; China, 39 tons; Japan, 47 tons; Argentina, 83 tons; Brazil, 77 tons; Canada, 16 tons; Chili, 46 tons; Cuba, 18 tons; Mexico, 30 tons; U.S.A., 14 tons; Australia, 18 tons.

**Carbon Filament and Nernst Lamps.**—Total weight, 242 tons. Value, £167,650. Number of lamps, 7,916,003. The chief countries exported to were:—Belgium, 16 tons; France, 17 tons; Great Britain, 45 tons; Italy, 16 tons; Austria, 16 tons; Russia, 43 tons; Argentina, 16 tons; Brazil, 8 tons; U.S.A., 2 tons.

**Telegraphic Apparatus (excl. Wireless).**—Total weight, 137 tons. Value, £48,200. The chief countries exported to were:—Holland, 9 tons; Russia, 31 tons; China, 8 tons.

**Telephonic Apparatus (excl. Wireless).**—Total weight, 957 tons. Value, £431,800. The chief countries exported to were:—Belgium, 66 tons; Denmark, 32 tons; France, 74 tons; Great Britain, 131 tons; Italy, 123 tons; Holland, 62 tons; Austria, 68 tons; Roumania, 21 tons; Russia, 130 tons; Switzerland, 47 tons; China, 25 tons; Argentina, 27 tons; Brazil, 25 tons.

**Electrical Fuses, Cut-outs, Bells, Signalling Apparatus, &c.**—Total weight, 1,048 tons. Value, £186,700. The chief countries exported to were:—Belgium, 106 tons; Denmark, 61 tons; Great Britain, 186 tons; Italy, 45 tons; Holland, 58 tons; Austria, 40 tons; Russia, 169 tons; Sweden, 49 tons; Switzerland, 42 tons; Argentina, 76 tons; U.S.A., 20 tons.

**Apparatus for Wireless Telegraphy and Telephony.**—Total weight, 277 tons. Value, £82,100. The chief countries exported to were:—Great Britain, 41 tons; Austria, 13 tons; Argentina, 11 tons; U.S.A., 24 tons.

**Electrical Devices for Lighting, Power, &c.**—Total weight, 21,553 tons. Value, £3,702,350. Among the countries exported to were:—Belgium, 1,465 tons; France, 1,121 tons; Great Britain, 1,441 tons; Italy, 1,205 tons; Austria, 1,992 tons; Russia, 2,924 tons; British South Africa, 273 tons; Argentina, 1,520 tons; Australia, 122 tons.

**Electro-Medical and Dental Apparatus.**—Total weight, 610 tons. Value, £228,200. Among the countries exported to were:—Belgium, 29 tons; France, 27 tons; Great Britain, 51 tons; Italy, 22 tons; Austria, 113 tons; Russia, 119 tons.

**Electrical Measuring Instruments, Electricity Meters, and Parts.**—Total weight, 3,321 tons. Value, £1,211,500. The chief countries exported to were:—Belgium, 129 tons; Denmark, 134 tons; France, 184 tons; Great Britain, 275 tons; Italy, 375 tons; Holland, 91 tons; Norway, 43 tons; Austria, 353 tons; Roumania, 26 tons; Russia, 570 tons; Finland, 46 tons; Sweden, 125 tons; Switzerland, 106 tons; Spain, 249 tons; British South Africa, 14 tons; China, 20 tons; Japan, 91 tons; Argentina, 279 tons; Brazil, 34 tons; Chile, 47 tons; U.S.A., 17 tons; Australia, 21 tons.

**Primary Batteries and Parts.**—Total weight, 1,807 tons. Value, £154,150. The chief countries exported to were:—France, 68 tons; Great Britain, 485 tons; Italy, 43 tons; Holland, 146 tons; Russia, 85 tons; Sweden, 252 tons; Switzerland, 135 tons.

**Electrical Heating and Cooking Apparatus and Parts.**—Total weight, 330 tons. Value, £83,750. The chief countries exported to were:—Austria, 42 tons; Russia, 53 tons; Argentina, 30 tons; Brazil, 18 tons.

**Asbestos, Mica, and Micanite Insulators.**—Total weight, 260 tons. Value, £56,300. The chief countries exported to were:—France, 53 tons; Great Britain, 45 tons; Austria, 33 tons.

**Insulating Tubes of Paper, &c.**—Total weight, 4,232 tons. Value, £163,300. The chief countries exported to were:—Belgium, 358 tons; Italy, 364 tons; Austria, 406 tons; Russia, 329 tons; Sweden, 367 tons; Switzerland, 1,253 tons; Argentina, 203 tons; Chili, 205 tons.

## ELECTRICAL EMPLOYEES WITH THE ARMY

VERY large numbers of the employees of electric supply, tramway, and manufacturing undertakings of Great Britain are now serving in the Army and Navy and Territorials. We give a few examples below. In many cases arrangements are being made to continue the full pay of the men in the case of married employees and half-pay to single employees, in other instances the difference between the Army pay and the ordinary wages is being paid, and in others the firm guarantees to look after the wives and families of the men. It will be seen that the tramway undertakings are supplying the largest numbers of men, probably for the reason that so many Army reservists find employment in this direction.

**London County Council Tramways.**—700 men, and an additional 400 men are liable to be called upon as National Reservists.

**Glasgow Corporation Tramways.**—604 men, including many members of the engineering staff.

**Birmingham Corporation Tramways.**—340 men.

**Manchester Corporation Tramways.**—346 men.

**Metropolitan Electric Tramways.**—233 men.

**London United Tramways.**—150 men.

**Liverpool Corporation Tramways.**—400 men. The deputy chairman of the Tramways Committee, Major R. J. Clark, is serving with the 9th Batt. the King's Liverpool Regiment.

**British Thomson-Houston Co.**—130 men from staff and works, including Commander H. G. Glennie, R.N., J. N. Macdonald (King's Horse), R. Waterhouse (6th Lancashire Fusiliers). It is anticipated that the number will eventually amount to 200.

**Birmingham Corporation Electricity Department.**—80 men, including the assistant mains engineer, Capt. R. B. Bowler, Royal Engineers (Territorials).

**Crompton & Co.**—150 men.

**Dundee Corporation Electricity Department.**—36 men, including Mr. G. Marshall, assistant mains superintendent, and several junior attendants in the generating and sub-stations.

**W. T. Henley's Telegraph Works Co.**—120 men, including the chief electrician at the Gravesend works, Mr. Leeseaux, and Mr. R. A. Hatton, engineer at Woolwich.

**North Metropolitan Electric Power Supply Co.**—33 men.

**South Metropolitan Electric Tramways and Lighting Co.**—25 men.

**Manchester Corporation Electricity Department.**—59 men.

**Glasgow Corporation Electricity Department.**—58 men.

**Automatic Telephone Manufacturing Co.**—50 men.

**Cardiff Lighting & Tramways Department.**—75 men.

**Belfast Corporation Electricity Department.**—25 men.

**General Electric Co.**—Many men from all departments, including the head of the Publicity Department, Lieut. H. Clifford Palmer, of the London Scottish.

**Siemens Bros. & Co.**—All departments have sent men.

**Edinburgh Corporation Electricity Department.**—30 men.

**The Volunteer Civil Force.**—We are requested to announce that members of the Volunteer Civil Force are prepared to offer their services in any part of the country for the protection of engineering works and electrical power stations, &c. In view of the possibility of rioting some satisfactory means of protection of private property should be found at once, and this they are prepared to do by sending trained men who have had experience in a similar direction. Full particulars will be forwarded on application to Ruskin House, Rochester Row, Westminster, S.W.

**The International Kinematograph Exhibition.**—It has been decided to postpone this Exhibition definitely until the first week in January—provisionally some time between December 26th, 1914, and January 6th, 1915—on the understanding that firms who have booked space for the present Exhibition shall renew their contracts for the succeeding one. This postponement has been made entirely in the interests of the trade, and the Exhibition authorities ask the trade for their help in the next Exhibition, in order to recoup them for the sacrifices made in postponing the present one.

**Future of London's Electricity Supply.**—The London County Council has suggested to the corporations and councils concerned in the proposed electricity scheme, of which we gave details in our issue for July 30th, that a conference should be held in October to go into details prior to the Council's application for Parliamentary powers.

**Electric Vehicle Charging Tariffs.**—Fifty-four municipalities and three electric supply companies have adopted a flat rate of 1d. per unit for charging electric vehicles.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no

award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,402.

Owing to the war conditions it is not surprising that no replies have been received.

### QUESTION No. 1,403.

What are the main requirements to be kept in view in the design of brush holders for large multipolar machines?

(Replies must be received not later than first post, August 20th.)

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published August 6th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

**Names in italics indicate communicators of inventions from abroad.**

15,875/13. **Starting Alternating-Current Motors.** *Ateliers de Constructions Electriques de Charleroi.* This specification describes an arrangement for starting cascade groups composed of an asynchronous machine with its rotor connected directly to the armature of a synchronous machine. A polyphase reactance is used, as well as a resistance to facilitate getting into synchronism. Five figures.

17,453/13. **Electric Heating and Cooking Apparatus.** *C. Clarke.* In this apparatus the utensil is constructed with a bottom of a special form to resist distortion by heat, and has a true flat or lenticular surface to make good contact with a surface of corresponding shape on the separate hot-plate. Seven figures.

22,222/13. **Arc Lamp Carbons.** *F. M. Lewis.* Arc light electrodes with a mixture of chemicals on the outer surface, including chromates as well as the usual mixture of tungstates and fluorides.

23,277/13. **A Magnetic Motor.** *E. W. Fuller.* This curious motor is to convert the pull of permanent magnets into rotation, and appears to amount to an attempt at perpetual motion. One figure.

27,354/13. **Car Lighting Dynamos.** *F. L. Hollister.* In these machines, the regulation is effected by a variable negative coefficient resistance in conjunction with a demagnetising coil for the variation of the field. Three figures.

5,281/14. **Production of Electric Waves.** *H. D. Dwyer.* An oscillator for the production of electric waves, comprising two thin hollow stationary electrodes with opposite parallel surfaces immersed in a vessel of imperfectly conducting liquid. One electrode has a small aperture through which the liquid, continuously drawn off and cooled, is projected against the other electrode. One figure.

6,418/14. **Condensers.** *A. E. G.* These condensers comprise layers continuously wound to form a spiral body. The conducting plates consist of strips with rounded edges, and of a thickness determined by the working voltage. One figure.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** *Fisher* [Jointing cables] 20,140/13; *Burton, Burton and Burton* [Metallic conduits] 4,583/14.

**Dynamos, Motors, and Transformers:** *Tattersall & Tattersall* [Starting and lighting motor-cars] 22,503/13.

**Heating and Cooking:** *Trenerz and Kingman* [Water heating] 19,803/13; *Paget* [Heating elements] 23,715/13; *Foster* [Heating elements] 24,565/13.

**Ignition:** *Varley* [Ignition, lighting, and starting system] 7,482/14; *R. Bosch* [Battery leads] 7,686/14.

**Incandescent Lamps:** *Kruger and Sannig* [Incandescent lamps] 27,771/13; *Voss, Mathe, and Burger* [Filaments] 6,037/13.

**Switchgear, Fuses, and Fittings:** *Fletcher* [Illumination of chart tables] 19,205; *Siemens Brothers Dynamo Works, Ltd. (Siemens Schuckertwerke)* [Switches] 28,633/13; *Heck* [Mounting bracket for switches] 3,900/13.

**Telephony and Telegraphy:** *Automatic Telephone Manufacturing Co. and Harrison* (partly *Automatic Electric Co., U.S.A.*) [Party line telephone system] 13,976/13; *Western Electric Co. (Woodward)* [Telephone machine switching] 16,696/13 and 24,928/13; and [Telephone repeaters] 25,659/13; *Siemens & Halske A.G.* [Automatic and semi-automatic telephone systems] 12,483/14.

**Traction:** *Meakin* [Signals] 19,205/13; *Gill and Davidass* [Train stop] 22,655/13; *Bottle* [Automatic signalling] 25,129/13; *Boirault* [Electric couplings] 196/13.

**Miscellaneous:** *Hirst and Jenkinson* [Signs] 17,265/13; *Entwistle & Kenyon, Ltd., Kenyon and Shorrocks* [Vacuum cleaners] 17,475/13; *Cambridge Scientific Instrument Co. and Arthorpe* [Galvanometers] 20,654/13; *Newton* [Magnetising permanent magnets] 24,327/13; *Siemens & Halske A.G.* [Electric riveting] 27,050/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos and Motors:** *Kettering* [Engine starters] 13,022/14; *Renault* [Engine starters] 15,464/14.

**Electrometallurgy:** *Geb. Siemens* [Manufacture of compounds of rare earth metals] 9,534/14; *Ozil* [Electro-deposition] 16,776/14.

**Ignition:** *Mueller* [Magnets] 4,562/14.

**Instruments:** *Szilard* [Electrometers] 16,945/14.

**Switchgear, Fittings, &c.:** *Chalier* [Theatre lighting fittings] 16,203/14; *Siemens Schuckertwerke* [Protective gear] 16,860/14.

The following Amended Specification may now be obtained:—

*J. G. Statter* [Time limit devices], 25,606/12; *B. T. H. Co. (G.E.C., U.S.A.)* [Annealing magnetic matter] 25,902/12; *F. Sahler* [Secondary battery plates] 8,469/13; *N. A. Halbertsma* [Arc lamps] 8,597/13.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors, and Transformers:** *F. N. Maude* [Generator] 9,571/09.

**Ignition:** *A. Just, F. Hanaman, H. Landesberger, J. Salzmann, and the Vereinigte Electricitäts A.G.* [Mounting filaments] 9,349/06.

**Instruments and Meters, &c.:** *V. A. Arcioni* [Meters] 8,518/01.

**Switchgear, Fuses, and Fittings:** *Lillicrop* [Motor starters] 8,752/08; *R. van R. Sill* [Controllers] 9,349/09; *Weckmar* [Cut outs] 9,803/09.

**Traction:** *M. Cummings* [Electric sanding gear] 9,270/07; *Daimler Motor Co. and F. W. Lanchester* [Petrol-electric vehicles] 9,259/09.

**Miscellaneous:** *C. Hollinghurst* [Signs] 9,250/09.

## ELIMINATION OF THE THIRD HARMONIC FROM THE WAVE FORM OF THREE-PHASE GENERATORS

THE troublesome effects of a third harmonic in the wave form of a three-phase generator when the neutral is earthed are too well known amongst electrical engineers, particularly the disturbing induction effects on telephone systems in the case of long-distance transmissions, and the circulating currents in the case of parallel running of two machines with earthed neutrals. Various methods of eliminating the third harmonic have been suggested, such as the special shaping of the pole shoes, and the irregular spacing of the slots; but the effective methods are too costly for practical application. To obviate telephone disturbances in the case of cable transmission an insulated metal sheath, such as the lead covering within an armoured cable, may be connected to the neutral; but for overhead work the trouble is more difficult to overcome. In the case of parallel running, arrangements may be made to earth only one

DIAGRAM OF CONNECTIONS.

machine, but these are generally unreliable. On the other hand, choking coils or resistances may be inserted in the earth connections to reduce the value of the circulating currents.

The most satisfactory solution of the problem, however, would be to eliminate the third harmonic altogether, and in the *Elektrotechnische Zeitschrift* of June 4th, Mr. R. J. Jensen, of Copenhagen, describes a comparatively simple method for new machines, which will doubtless be adopted to some extent in the future. It consists in dividing each phase of the three-phase winding of the generator into two equal parts, and then connecting the six windings in zig-zag, exactly as is done in the case of three-phase transformers for the purpose of balancing an unsymmetrical load. The connections are made according to the accompanying diagram, in which I., II., and III. represent the three (phase) windings of the generator. Each is divided into two portions, 1 and 2, and it is necessary, therefore, that the machine should be designed with an even number of slots per pole per phase. A third harmonic is generated in each of the six windings in the direction  $a$  to  $e$ , and the two harmonics cancel out, therefore, in each phase. The resultant E.M.F. of the fundamental wave is smaller than the E.M.F. of the original machine in the ratio of  $\sqrt{3}$  to 2, and so for the same output this machine will require 6 per cent. more copper. The armature reaction remains the same, but the ohmic loss and the inductive drop will each be 6 per cent. greater. The iron losses will be 15 per cent. greater. In addition, the author remarks that three-phase transformers wound zig-zag for purposes of balancing are in the same way impenetrable to third harmonics, and the neutral can therefore be earthed without fear of disturbances to telephone circuits.

## NATIONAL SERVICE

THE Council of the Institution of Electrical Engineers is sending out a circular suggesting that there are two important directions in which the members and also electrical men who are not members may be of service to the nation at the present time: By placing their services as electrical engineers at the disposal of the War Office and of the Admiralty, and by holding themselves in readiness to fill vacancies in public services, electric power stations, tramways, railways, &c., caused by the calling up of the Reserves and Territorial Forces. The Council have decided to prepare classified lists of suitable men for this purpose, and in this connection are issuing forms to be filled in with particulars of the kind of work for which applicants are fitted. It is

assumed that the rates of pay would be the current rates for the services rendered. The Council desire not only to receive offers of services from members of the Institution, but also that all members should assist them to obtain the names of as many qualified men as possible (whether or not members of the Institution) willing to offer their services. The Council have offered to place at the disposal of the War Office, for immediate occupation and free of charge, the available portions of the Institution building, of a total area of 10,000 sq. ft.

Those applying are requested to supply the following particulars:—Name, class of membership, address, nationality, age, number of days' notice required before duties can be taken up, whether single or married, present occupation, place of occupation, present employer, address of present employer; military, naval, or marine experience and status (if any); foreign languages; and whether services are offered for army (abroad or at home), navy (shore duties), or to fill vacancies in connection with public services, electric power stations, tramways, railways, &c., in own locality or elsewhere in the United Kingdom.

The applicant is further asked whether he is prepared to undertake supervising work or actual manual work, and to state for what trade he is qualified. The various occupations are scheduled as follows:—Erection, running, repairing, or testing of: boilers and boiler-room plant; steam engines; turbines; gas and oil engines; dynamos, motors, transformers; heavy electrical plant, cranes, winches, &c.; electric light and power installations; switchboards; traction, track, and overhead work; locos. and rolling stock; cables; mains and services; overhead power lines; telegraph and telephone lines; telegraph apparatus; wireless apparatus; telephone apparatus; light electrical plant or apparatus; searchlights; military and naval signalling; electric blasting apparatus; Röntgen apparatus; inspection of electrical machinery and apparatus and passing same for purchase; coding and decoding of telegrams.

## END OF THE WIREMEN'S STRIKE

WE have received the following letter from Mr. L. G. Tate, hon. secretary of the London Electrical Masters' Association:—

"I have pleasure in notifying you that the strike of electrical wiremen in London initiated by the Electrical Trades Union on April 1st is now at an end, the members of the Union having been instructed to return to work. The working rules issued by the London Electrical Masters Association in March, 1914, have been adopted for a further six months, and a joint committee of masters and men will be appointed to adjudicate on any questions of hardship that may be brought forward. I may add that these proposals were put forward by the masters in the early part of April, but were then refused by the Union."

## CORRESPONDENCE

### THE ELECTRICAL TRADES BENEVOLENT INSTITUTION.

To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—At the present moment there must be a considerable number of firms whose staffs have been somewhat depleted by the calls on the Territorials and also the departure of foreigners to their countries. As this Institution is now assisting four or five gentlemen who would be capable of occupying such positions for the time being, I shall be glad if through your columns you could induce firms requiring any of these to communicate with me. This will have a double advantage, first, providing work for persons who are wanting it, and secondly, enabling this Institution to husband its resources, a step which is more necessary than ever at the present time. I may add that I regret to hear from one of those we have assisted in the shape of helping the man and his wife to set up lodgings, that owing to the war a German lodger who was sent to them by an electrical firm has had to go, and they are thus again placed in pecuniary difficulties. Their house is close to one of the South London Tube stations.

18, Park Mansions,  
Vauxhall Park, S.W.,  
Aug. 6th, 1914.

Yours faithfully,  
F. B. O. HAWES,

Secretary,  
The Electrical Trades Benevolent  
Institution.

**The B.E.A.M.A. and Admiralty and War Office Orders.**—Immediately after the outbreak of hostilities, the Council of the B.E.A.M.A., on behalf of the members, wrote to the Admiralty and War Office offering to use every endeavour towards expediting Government contracts. The Council have no doubt that their action will meet with the hearty support and approval of every member of the Association.

## AIR GAPS OF ELECTRIC MOTORS

THE above is the title of a Paper recently read before the Association of Mining Electrical Engineers (North of England branch) by Mr. C. Lewis. The substance of the Paper is a plea for larger air-gaps than are usually found in recent induction-motor practice. The reason for the meagre air-gaps which are at present used is that a large air-gap means a larger, and therefore more expensive, motor for the same output. Mr. Lewis recommends that the makers of induction motors should be asked to stipulate the length of air-gap they employ in their machines, so as to enable the prospective purchaser to form a correct estimate of the relative capabilities of the latter. With a very small air-gap, a slight amount of eccentricity of the armature between the poles will cause a serious inequality of flux distribution, and consequently local armature currents will be set up. In the case of D.C. machines, however, a definite length of gap is necessary to provide reluctance in the path of the cross flux of the armature, so that the space has not been reduced to the fine limits which are found in induction motors. The use of a larger gap entails a reduced efficiency and a higher first cost. The advantage gained by its adoption is greater immunity from breakdown, and whether large or small air-gaps are desirable will depend upon the capital cost of the plant and subsequent maintenance charges, and the importance of reliability.

Dealing with the case of a consumer using town supply, the author showed that as a large gap only increases the magnetising current which is the wattless component of the load, its adoption would be a distinct advantage to the consumer. In the case of a colliery company generating their own power, this wattless current has to be considered, owing to its undesirable effect upon the power-factor. There will be a certain length of gap beyond which it will not be desirable to go. In conclusion, however, the author ventures to prophesy that the adoption of a reasonable air-gap would ensure such a continuity of service and saving in depreciation costs as would largely compensate for the increased initial cost, as well as raising the prestige of the induction motor generally.

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

WE have received a copy of the prospectus of the University courses at the Municipal School of Technology, Manchester, the Electrical Engineering Department of which is under Prof. Miles Walker. The training is of a particularly broad and practical kind, and several members of the staffs of manufacturing firms take part in the teaching. Among the subjects of lectures may be mentioned works management, costing, the calculation of electric winding engines, switchgear, &c.

The prospectus of the Faculty of Engineering of University College, London, gives particulars of the courses for the forthcoming session. The Electrical Engineering Department is under Prof. J. A. Fleming, F.R.S., assisted by Prof. W. C. Clinton and Mr. P. R. Coursey. Mr. E. Kilburn Scott also gives lectures on electrical design. The ordinary course qualifies for the London B.Sc. degree, and there are special opportunities for post-graduate and research work.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Since our last issue, notices concerning the state of telegraphic and radio-telegraphic communications have been numerous, and are likely to become still more so as other States and countries become involved in the great European struggle.—On the 4th inst. private telegrams to Switzerland and in transit *via* that country had to be written in plain German, French, or Italian, while those without text or signature are not admitted. There is also delay owing to Government censorship.—The Belgian Administration stated on the 5th inst. that telegrams in code or cipher were totally suspended to and from Belgium.—Turkey on the same day refused to admit telegrams in code.—The Government of the Union of South Africa, under Article 8 of the International Telegraphic Convention and Article 17 of the Radio-telegraphic Convention, until further notice only admits telegrams and radio-telegrams to, from, or in transit over their lines written in plain English, French, or Dutch. They must be signed by the sender. Abbreviated addresses are not permitted. Messages in plain language are accepted at sender's risk, but British Government telegrams are not submitted to any restrictions.—France also only accepts private tele-

grams for France and Algeria at sender's risk, and only when written in plain German, English, Spanish, French, Italian, Portuguese, or Russian. They must be so worded as to offer an intelligible meaning to the telegraph service. They are subject to delay and to censorship.—Telegraphic and telephonic communication is also suspended between Belgium and Germany.—On the 6th inst. the British Government confirmed that all telegrams must be written in English or French, and that they are accepted at sender's risk, subject to censorship. They may be stopped, kept back, or treated as of no consequence whatever, and no advices will be issued to the sender. Applications for refunds will not be considered, whatever their nature may be. It is very important that all telegrams bear the signature of the sender at the end of the telegram, as otherwise they are held till the name is supplied by paid service advice.—On this day, also, the Western Telegraph Co. suspended the deferred and week-end letter service.—Censorship was established at Madagascar, telegrams in code or cipher not being admitted.—By reason of lines being much encumbered between Rome and Zante, telegrams in transit for Italy and routed *via* Zante are subject to great delay, and are only accepted at sender's risk.—Communication also between Berlin and St. Petersburg, Teheran and Tokio is interrupted.—The Commercial Cable Co. states that they are only able to accept on their lines telegrams fulfilling the conditions imposed by the British Government.—The French Government, according to Articles 8 and 17 of the Telegraphic and Radio-telegraphic Conventions, only accepts messages for Algeria and French Colonies and Protectorates in plain French or English, and bearing the sender's signature. They are accepted at sender's risk, and applications for refunds cannot be entertained. Secret language can only be used for Government telegrams of France, Great Britain, Russia, and Belgium.—The Commonwealth of Australia, according to the above-mentioned Articles, has decided to suspend all telegrams to, from, and in transit over its lines, excepting British or Australian Government messages. As an act of grace, however, until further advice telegrams in plain English or French are accepted at sender's risk, and subject to censorship, and they must bear the signature of the sender, but abbreviated addresses are not permitted.—The Ottoman Administration on the 7th inst. stated that all telegrams arriving contrary to notices are held up without advice to senders.—The Compagnie Française des Câbles Télégraphiques has suspended the deferred service.—The French Government state that lines between Belgium and Luxembourg are interrupted, and that secret language is admitted on French lines for Italian and Spanish Government messages. Telegrams for Turkey can only be written in Turkish or French. Secret language is only permitted for diplomatic and consular telegrams.—The Great Northern Telegraph Co. has also suspended the deferred service.—On the 8th inst. the Netherland Indies Government stated that Government telegrams in plain or secret language are admitted for all non-belligerent countries.—All communication with Germany, Austria, and Hungary is cut off, and the Eastern suspended the deferred and week-end service on the 5th inst., and the South American Cable Co. on the 9th.—Communication between Hungary and Montenegro is down.—The Servian Government state all telegrams are accepted at sender's risk, and must only be in plain language. This also refers to telegrams in transit.—The Austrian Administration states that telegrams for France, Great Britain, Belgium, and places beyond these countries, as well as their possessions and Protectorates, cannot be routed *via* Austria.—The Ottoman Office on the 10th inst. confirmed that plain Turkish, Arabic, and French are only admitted for private telegrams, which must have full address and signature. Telegrams without text are not admitted, and no advices are sent to senders of telegrams contrary to regulations being stopped.—The administration of Indo-China states on the 11th inst. that telegrams to, from, and in transit for Indo-China must be sent in plain intelligible French or English, the name of the sender appearing after the text. Abbreviated addresses are not now permitted, and the deferred service is suspended. Telegrams for Germany and Austria are prohibited.—The Great Northern Telegraph Co. confirms the suspension of deferred telegrams on their lines.

The *Morning Post* points out that the capture of Togoland by the British Forces deprives the Germans of the use of the large Telefunken wireless station there. Regular communication has been maintained between this station and Nauen since May.

The Committee for Radiotelegraphic Investigation of the British Association announces that the proposed observations during the total eclipse of the sun on August 21st have been abandoned owing to the war.

## "ELECTRICAL ENGINEERING" TRADE SECTION

### OSRAM HALF-WATT LAMPS FOR LIGHTHOUSES

THE use of Osram half-watt lamps in lighthouses has proved most satisfactory, as the light emitted by these lamps is very penetrating, and, since the filament is concentrated in a small space, focussing is particularly easy. The illustration shows a 8,000-c.p. Osram half-watt lamp in a lighthouse on the end of the Port Talbot Dock and Railway Co.'s pier. This is badly exposed to the weather, but the lamp has not

LIGHTHOUSE AT PORT TALBOT EQUIPPED WITH 3,000-C.P. HALF-WATT LAMP.

suffered. A 1,000-watt 1,000-c.p. Osram drawn-wire lamp was first installed, and the pilots were able to pick up the light when off the Mumbles Head, a distance of between 4½ and 5 miles. This lamp was superseded by the 1,500-watt 8,000-c.p. Osram half-watt lamp, and the pilots are now able to pick up the light when about seven miles down channel. An Osram half-watt lamp installed on the pier-head at Dunoon has also stood up to the very severe weather conditions without any protection whatever.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**CHAINS.**—An effective wall sheet entitled "The Care of Chains and the Prevention of Accidents" is being issued by Weldless Chains, Ltd. (Gartsberrie, Coatbridge), and will be sent post free to any firm who applies for a copy.

**HEATING AND COOKING APPARATUS.**—An illustrated leaflet from R. H. Haylock & Son (63 Queen Victoria Street, E.C.) describes an electric stove, grill, and immersion heater known respectively as El Glo, Stovo, El Grillo, and El Boilo, and a hot-point electric iron.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**MOTOR STARTERS.**—Leaflets from the Electrical Apparatus Co., Ltd. (Vauxhall Works, South Lambeth Road, S.W.), contain particulars of the latest types of standard types of motor starters manufactured by this firm. The company states that owing to all their material being purchased in England, their deliveries will be very little affected by the war.

**ELECTRIC CARS.**—A handsomely illustrated booklet entitled "The Silent Waverley Electric Year Book" describes some

luxurious electric carriages made by the Waverley Company of Indianapolis.

**MAZDA HOUSE NEWS.**—The July-August issue of this bright little journal gives interesting information of the newest types of Mazda lamps and other novelties of the British Thomson-Houston Co., and a number of views of up-to-date lighting installations.

**INSULATORS.**—A very large number of patterns of insulators are described in a new catalogue from Doulton & Co., Ltd. (Lambeth, S.E.). All these are British made, and deliveries can be given as usual.

### TENDERS INVITED AND PROSPECTIVE BUSINESS

#### Generating Stations, Sub-Stations, Mains, &c.

**Aylesbury.**—Subject to the Board of Trade approving the proposed site of the generating station, the Local Government Board will sanction a loan of £21,323 for the Council's electricity undertaking.

**Blackburn.**—A new power station is contemplated.

**Bolton.**—An expenditure of £600 is contemplated, upon cable, services, &c.

**Burnley.**—New cable at an estimated cost of £540 is required.

**Cheadle and Gatley.**—A report is being prepared as to taking a supply in bulk from Stockport, and alternatively, for Stockport to supply in detail.

**Clacton.**—Cable extensions are recommended.

**Gobham.**—The Ascot District Gas and Electricity Co. is proposing to supply in this district. An offer has also been received from the Woking Electric Supply Co. The Ascot Co., however, has statutory powers in the district.

**Earsdon.**—Poles, cables, lamps, &c., for public lighting. Clerk. August 15th.

**Eastbourne.**—A sum of £4,000 is to be spent on replacing certain plant at the power station.

The new plant will consist of a 500-kw. turbo-alternator for running on light load in lieu of the reciprocating engine set now used for this purpose. The Borough Electrical Engineer reports that the running of such a set would effect a saving of £918 per annum, compared with the present cost of the reciprocating engine. The capital expenditure is to be met partly out of the renewals fund and partly out of the reserve fund.

**Gillingham.**—Sanction to a loan of £7,500 for mains and services is to be applied for.

**Hereford.**—The L.G.B. has sanctioned a loan of £1,500 for mains, repayable in twenty-five years, and £1,080 for miscellaneous works at the power station.

**Mold.**—Communications are passing between the Clerk and the Town Clerk of Flint with regard to the proposed electric lighting scheme.

**Portrush.**—The Council, which possesses an electric lighting provisional Order, is recommended to instal two 55-h.p. suction gas engines driving two 33-kw. dynamos, with battery, booster, and balancers, in the proposed power station. Messrs. J. Woodside & Co., of Belfast, are consulting engineers. The scheme includes public lighting, consisting of sixty-five standards each fitted with two 80-watt metal filament lamps, and thirty-one each fitted with a 60-watt lamp.

**Turton.**—An expenditure of £600 is contemplated upon cables.

#### Wiring

**Dundee.**—Electric lighting of Harris Academy Public School. Clerk, School Board Offices. August 15th.

**Edinburgh.**—Electric lighting of public wash-house, Green-side. City Electrical Engineer. August 17th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Accorington.**—Fire station, Manchester Road.

**Altrincham.**—Council school. Cheshire County Architect.

**Barnsley.**—School. Architect, E. W. Dyson, Regent Street.  
**Blackburn.**—New fire station.  
**Farnworth.**—Secondary school. County Architect, Preston.  
**Manchester.**—Co-operative stores. Ashton Old Road. Architect, J. B. Thornley.—Cinematograph theatre. Rusholme. Architects, Mangall & Littlewood.—New works and offices. Ashton New Road. Architect, W. H. Longworth.  
**Paignton.**—Extensions to isolation hospital (£2,537).

### TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Manchester.**—Among the tenders recently placed by the Electricity Department are the following:—Cable, British Insulated & Helsby Cables, Ltd.; Electrical Engineering & Equipment Co.; Union Cable Co.; W. T. Glover & Co. Lamp-holders, shades, switches, fuses, B.T.-H. Co. Tumbler switches, General Electric Co. Insulating tape, W. T. Glover & Co.; W. T. Henley's Telegraph Works Co.; and India-Bubber, Gutta Percha and Telegraph Works Co. Compound, Callender's Cable and Construction Co.

**Middleton.**—The tender of E. Green & Son has been accepted for economisers at the power station.

**York.**—The following tenders have been accepted by the lighting and tramways department:—Rotary-converters, transformers, and connecting cables, General Electric Co.; switchgear, B.T.-H. Co.

### LOCAL NOTES

**Eastbourne:** *Charging Electric Vehicles.*—A 50-kw. dynamo at the power station is to be converted into a charging set for electric vehicles. The tariff has been fixed at 1½d. per unit.

**Glasgow:** *Electricity Accounts.*—After meeting capital charges and setting aside £52,171 for depreciation, there was a net profit of £819 upon the Corporation electricity undertaking last year. The average price received per unit was 1'157d., a reduction of 0'13d. per unit compared with the previous twelve months.

**Hove:** *Progress of Electrical Undertaking.*—The Engineer and Manager of the Council's electricity undertaking reports most satisfactory progress for the first quarter's working under municipal control. The total revenue was £4,149 as against £3,771 in the corresponding quarter of last year, whilst the works costs have decreased from £1,135 to £1,095. This result has been achieved, notwithstanding that this quarter is the lightest one of the year. Further economies are looked to when the new generating station is installed, and the question of the reduction of tariff is being considered in view of this.

**Kingstown:** *Electric Lighting.*—The Council has decided to purchase the electric lighting provisional Order granted this session to the Dublin & Southern District Electric Supply Co.

**Manchester:** *Efficient Library Lighting.*—As the result of a re-arrangement of the electric lighting in the Corporation libraries, a reduction of 50 per cent. in the current consumption has been brought about, together with a saving of £1,000 in the annual cost.

### APPOINTMENTS AND PERSONAL NOTES

The Oldham Corporation has appointed Messrs. Ogden and Chamberlain Joint Borough Electrical Engineers in succession to the late Mr. S. W. Newington.

The Maidstone Electricity Committee recommends that the present system of paying the Borough Electrical Engineer a bonus according to the profits of the undertaking be abolished, and that Mr. Hoadley's salary, as from April 1st, 1914, should be £550 per annum.

Mr. Edgar Kent succeeds Mr. F. Barlow as Superintendent of the Meter and Electrical Testing Department at Salford, at a commencing salary of £150 per annum, rising to £200.

Mr. F. Birch has been appointed Superintendent of the Motor-Hire Department.

A shift engineer is required by the Stretford U.D.C. at a commencing salary of £2 per week. Experience in D.C. combined traction, lighting, and power station necessary.

The Hele-Shaw prizes in the Faculty of Engineering of the University of Bristol have been awarded to J. Rogers, day student, and A. G. Adams.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Although the Metal Exchange is still closed and there is no official quotation for copper, the price may be taken as between £68 and £70.

**Dissolution of Partnership.**—Messrs. F. J. Allen and E. C. Beman, trading as The Electric Supplies Co. (53 Victoria Street, S.W.), has been dissolved. Mr. Beman will continue the business.

**The Marconi Press Agency.**—The expansion of this side of the Marconi Co.'s work has necessitated extension of its premises on the ground floor of Marconi House, facing Aldwych. The name will be changed to Wireless Press, Ltd., under which style the publication of the *Wireless World* and various books, &c., on wireless telegraphy will be continued.

**Belling & Co.**—Messrs. Belling & Co. inform us that, although they have at the moment nearly a thousand complete electrical fires in stock ready for delivery, and an equal number of sets of parts in different stages of completion, they are still keeping their hands at work assembling more fires for stock.

**Liquidations.**—The British Economical Lamp Co., Ltd., has gone into voluntary liquidation for reconstruction. Mr. H. E. Leigh, Windsor House, Kingsway, W.C., is liquidator.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Yorkshire Electric Power Co.**—The net profit for the six months ended June 30th was £10,414, against £6,972 in the previous half year. Including the balance brought forward the sum available is £14,602, which is reduced to £12,352 after meeting second mortgage bonus. As already announced, 2 per cent. is to be paid on the ordinary shares, in addition to the 6 per cent. preference dividend. The second 3,000-kw. turbine in the Waste Heat Station at Barugh has now been put on load, and mains are being laid in a large number of other stations. Supply has also been given since July 9th in Goole for railway, dock, and general purposes.

**London Supply Companies' Dividends.**—The directors of the Metropolitan Electric Supply Co. announce that although under ordinary circumstances they would have no hesitation in declaring an interim dividend at the same rate as last year, viz., 4 per cent. per annum, they have decided that it is in the best interests of the Company to defer the payment of any dividend on the ordinary shares for the present.—An interim dividend at the rate of 9 per cent. per annum is recommended by the Brompton & Kensington Electricity Supply Co.

**National Electric Construction Co.**—The report for 1913 shows a net profit of £4,827, which it is recommended shall be carried forward. The auditors in their report recommend that the expenditure upon the tramway and lighting concessions at Folkestone and West Yorkshire, viz., £39,932 and £845 respectively, should be written off, as they are now ascertained losses. In view of this recommendation, the directors have considered the need for a re-valuation of the whole of the Company's assets, and now suggest that the £1 shares of the Company should be reduced to 10s.

### NEW COMPANIES

**ELECTROMOBILE (LEEDS)**, 30 Bath Road, Holbeck, Leeds. Capital £1,000. To make and hire electric cars.

**"DAC" ACCUMULATOR SYNDICATE**, Cheshunt Wharf, Cheshunt. Capital £1,000. To acquire patents from the liquidator of the existing "Dac" Accumulator Syndicate.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

WE give further instances of the large number of electrical employees who are serving with the Army and Navy. (Page 461.)

An article by Mr. E. P. Hill deals with certain errors in the arrangement of equalising connections of compound generators that are sometimes met with. (Page 462.)

THE meeting of the British Association in Australia is now in progress. (Page 462.)

WE appeal to British manufacturers not only to manufacture for stock in advance of demands which may confidently be anticipated, but also to use every endeavour to introduce their products immediately in foreign and colonial markets before the business hitherto done with Germany is placed elsewhere. (Page 463.)

In a special article, we review the effect of the war upon the electric lamp industry. It is shown that an almost immediate increase in output may be anticipated, and manufacturers who have not their own glass works are advised to make arrangements for obtaining sufficient supplies of bulbs. Two only of the existing lamp works in this country have their own glass works, and hitherto the greater number of the remainder have had to obtain their bulbs from Germany. (Page 463.)

A QUESTION relating to charge and discharge meters for battery circuits is given in our Questions and Answers columns. (Page 464.)

THE specifications published last week included one dealing with an improved telephone repeater for wire-less work by the Western Electric Co.—The Board of

Trade has been empowered to suspend the patents owned by subjects of any State at war with this country.—A patent for a fire-extinguishing system expires this week after a life of fourteen years. (Page 464.)

THE B.E.A.M.A. has sent a circular letter to the principal large purchasers of electrical plant pointing out the necessity for the continuance of work under all possible contracts. (Page 465.)

NOTES on the arrangements for the next session at some of the Universities and Technical Colleges are given on page 465.

WE are able to give further information as to the interruptions in telegraphic communication due to the war. (Page 465.)

THE equipment of a municipal substation, a new traction lamp, and special designs of searchlights for civil purposes, are described in our Trade Section. (Page 466.)

TRANSFORMERS are required at Rochdale, rotary converters and switchgear at Dundee, and storage battery, &c., at Oldham. Extensions are also to be carried out at Newport (Mon.), Belfast, and Dublin. Tramway permanent way is required at Brighton and Bury. (Page 467.)

THE Dover Corporation has entered into a new agreement for supply to the Admiralty.—Satisfactory results for the past year's working are reported from Portsmouth and King's Lynn. (Page 468.)

W. T. HENLEY's Telegraph Works Co. announce a 10 per cent. interim dividend. (Page 468.)

OWING to many of the leading London tradesmen having had their horses commandeered for military purposes, practically the whole stock of electric vehicles has been cleared out. (Page 468.)

## ELECTRICAL EMPLOYEES WITH THE ARMY

WE give below further instances of electrical employees who are now serving in the Army and Navy and Territorials.

*Siemens Bros. Dynamo Works* (including all works and offices).—Between 130 and 140 men. Full wages are to be paid to married men and half to single men.

*British Electrical Federation*.—849 men from the federated companies in Great Britain and the head office staff of the Federation. (This includes the figures given last week for the North Metropolitan Electric Power Supply Co., the Metropolitan Electric Tramways, and the South Metropolitan Electric Tramways & Lighting Co.) The B.E.F. Mutual Aid Fund, for the relief of dependents of tramway and electric supply men who are called on service has been established by about forty of the federated tramway and electrical companies. It provides for the companies subscribing an amount equal to the total contributions made by the employees who remain at work. The contributions of the companies will not be less than 3d. per week in respect of every man in their employment. The men who have been called out have been given to understand that their places will be kept open for them upon their return. In the event of a reduction of services becoming necessary, the companies will endeavour, by equalising the work as much as possible to avoid reduction of staff.

*General Electric Co.*—100 men from Witton and Birmingham.  
*Ferranti, Ltd.*—70 men.

*Liverpool Corporation Electricity Department.*—All men called out will be reinstated without loss of position or emoluments consequent on their enforced absence. The Corporation will make up the difference between the Government pay and full salary or wage.

*Edison & Swan United Electric Light Co.*—17 men, including one in the Royal Flying Corps.

*British Insulated & Helsby Cables, Ltd.*—300 men.

*Dundee Corporation Electricity Department.*—In addition to the 36 men, including the assistant mains superintendent referred to in our last issue, Mr. H. Richardson, the General Manager of the Department, who resigned from the Royal Engineers a few weeks ago, has rejoined, and has been appointed Commanding Royal Engineer for the Dundee district.

*St. Anne's-on-Sea Corporation Electricity Department.*—A number of men have been called up for service in the Royal Naval Reserve. The Town Council will pay the wives and dependents £1 per week, and an allowance for each child, and situations will be kept open.

*Yorkshire Electric Power Co.*—An allowance is to be made for the wives and children of men called up.

*County of London Electric Supply Co.*—Half wages, with a minimum of £1 per week in respect of all men called up.

*India Rubber, Gutta Percha & Telegraph Works Co.*—Half wages will be paid to the wives and dependents of all employees called up, and employment will be found for them on their return.

## EQUALISING CONNECTIONS ON COMPOUND D.C. GENERATORS

By E. P. Hill

IT has been found, during a period of several years' outside work for a large manufacturing company, that a frequent source of trouble, and even of serious damage to expensive electrical plant, lies in the incorrect knowledge of the function and position of equalising connections. A crop of instances of this kind having recently been brought to the writer's notice, it is hoped that, should any others profit by this article, its aim shall have been fulfilled. In these days of severe competition and specialisation, the switchboard controlling the generating plant is frequently manufactured by another contractor than the machines, and in consequence the engineer representing the customer is responsible for the correct fusion of ideas between the control apparatus and machines.

With all respect to these gentlemen, one sometimes finds they are so occupied in keeping scrap plant in operation, &c., that they fail to enter very deeply into the details necessary for the switchboard designer to arrange matters satisfactorily to suit local conditions, and in consequence the standard design is submitted.

This usually consists of a D.P. switch and a S.P. circuit-breaker, together with the usual meters, &c., for each machine. Should, in the existing plant, the equaliser main be on the positive side, it is frequently found that the circuit-breaker is arranged in the new plant on the positive side, and trouble will develop from the following causes. Referring

FIG. 1.—EQUALISER  
WRONGLY  
CONNECTED.

FIG. 2.—CORRECT  
CONNECTION OF  
EQUALISER.

to Fig. 1, it will be noticed that, should for any reason the circuit-breaker operate, the other machine is still capable of receiving power through the equaliser main. I have known instances of machines flashing over from this cause, the trouble being put down to quite innocent causes for lengthy periods of time.

The second trouble which arises in this connection is that the ammeter is usually connected in the same main as the circuit-breaker. The result is that with the equaliser being on the same side, the ammeters are equalised independently of the actual loads on the various machines in parallel. I have seen steam engines motored for lengthy periods by the other set in parallel, the ammeters indicating, however, apparently that the load was equally divided.

The policy of restricting the size of the equaliser is not good, and engineers should err on the side of liberality in copper section.

The rule to be observed, therefore, is that ammeters and circuit-breakers (if S.P.) must be connected up in the opposite polarity from that of the equaliser main, or their functions become useless when parallel running is attempted.

Should it be found that, by oversight or error such a condition obtains, the best method to overcome the trouble is to flash over the polarity of old plant, and reverse the cables at the switchboard, thus bringing the existing equaliser into the negative side (as S.P. breakers are usually in the positive). If this be not practicable, the ammeter must be changed over to the other main, and an additional S.P. breaker added to make D.P. breaker, thus ensuring that power will be cut off when excessive overloads occur.

## THE BRITISH ASSOCIATION IN AUSTRALIA

THE meeting of the British Association for the Advancement of Science in Australia has not been affected by the war, and is now in progress, and several of the sectional presidents' addresses have already been delivered in Adelaide and Melbourne. Sir Oliver Lodge gave an evening discourse on "The Ether of Space," on August 10th, at Adelaide, and the first part of the address of the President of the whole Association (Prof. W. Bateson) was given on Friday of last week at Melbourne. The meetings of Section G (Engineering), in which our readers are more particularly interested, are distributed between Melbourne and Sydney, where Prof. Coker's presidential address will be given to-morrow, and a joint discussion with Section A on wireless telegraphy will be held. The Papers down for reading before Section G include the following:—"Proposed Metropolitan Electric Railway," by Mr. J. J. Bradfield; "The New Engineering Laboratories of the City & Guilds Engineering College," by Prof. W. E. Dalby; "Railways and Motive Power," by Prof. W. E. Dalby; "The Capacity of Radio-telegraph Aerials," by Prof. G. W. O. Howe; and "The Limiting Conditions for the Safe Use of Electricity in Mining," by Prof. W. M. Thornton. The following Papers in the programme of Section A may also be mentioned:—"A Mechanical Analogue of Wireless Telegraphic Circuits," by Prof. T. R. Lyle; "The Pressure upon the Poles of a Carbon Arc," by Prof. W. O. Duffield; "Some Measurements of the Wave-Length in Air of Electrical Vibrations Associated with a Thin Straight Terminated Rod," by Prof. J. A. Pollock. Sir Ernest Rutherford will give an evening discourse at Sydney on "Atoms and Electrons," and one on "Wireless Telegraphy" will be given at Brisbane by Prof. G. W. O. Howe. The meetings will conclude on August 31st.

**Payment for Foreign Material.**—The rights of our enemies, the Germans, in civil courts, as an outcome of the war, has been the subject of special applications in one or two cases of non-electrical interest. On Monday, however, the question arose in connection with a pending action by the Fabrik Elastischer Glühkörper (Elastic "Incandescence Bodies" Works) against the Imperial Lamp Works (Brimsdown), Ltd. The action was for the recovery of £900 for goods supplied, but on behalf of the Imperial Lamp Works, in chambers it was contended that the plaintiffs, being "alien enemies," could not be heard in the courts. In previous cases it has been held that such actions must be "suspended," and it was argued that this did not merely mean a "stay" until peace was declared. On the other hand, it was agreed that the suspension of civil rights was only temporary. Sir John Macdonnell, the Master in the Supreme Court, who heard the application, granted a "stay" with liberty to apply later. The costs of the application were reserved.

**The Motor-Car Trade and the Supply of Magnetos.**—An important meeting of British motor manufacturers was held in Coventry on Wednesday, the 12th inst., for the purpose of making arrangements for the supply of magnetos for motor-cars and motor-cycles. As is well known, large numbers of these have been purchased in the past from Germany, but, of course, this channel of supply is now stopped. A representative committee was appointed to communicate with English electrical firms with the view of obtaining supplies of magnetos in the future, and all firms desirous of entering into these important branches of the motor trade are requested to apply to the Convener of this meeting, Mr. Harry Smith, The Rover Co., Ltd., Coventry. It may be added that some important British firms have already expressed their intention of going into this trade.

**The Incorporated Municipal Electrical Association.**—The Proceedings of the Incorporated Municipal Electrical Association, containing a full report of the recent Birmingham Convention, have now been published.

### AN APPEAL TO MANUFACTURERS

THE events of this month have placed upon manufacturers a responsibility almost as great as that placed upon our Army and Navy. The exhortation to "carry on," and the motto "Business as usual" are being given to them so much as a matter of course that they are becoming little more than catchwords, and yet far more is needed from the manufacturer than these phrases imply if he is to do the utmost service to his country and the best he can for his industry in the present crisis. In the majority of cases business cannot be "as usual," and "carrying on" must be under very different conditions than before the outbreak of hostilities. The slight shortage of workmen due to the calling out of the Reserves and Territorials is not serious, and the duties of the other employees who have joined the colours can also be carried out by those who have had to remain at home; but there are, of course, other respects in which the manufacturer finds himself handicapped. Foremost among these is the financial position. Payments have to be made for wages and current establishment charges, and in the meantime payments from customers are apt to be delayed. Materials have to be bought, and, in some cases, alas, the suppliers of these demand cash or insist on very short credit, for they in their turn are met with a momentary shortage of raw material, or a demand for quick payments from the producers or importers. There is also a natural tendency for both the retail and wholesale customer to limit his requirements to the smallest possible dimensions, and the manufacturer is loth to manufacture for stock under the present adverse conditions, even in the case of standard articles which must eventually be required.

We appeal to the manufacturers to show their patriotism by fighting against these tendencies to inaction. Not only is there already much work to do in manufacturing several classes of stocks which will inevitably be demanded, but there is also much to do in finding and fostering new markets which must exist under the new conditions. Last week we published detailed particulars of the German export to foreign and colonial markets now open to us, and the enormous imports of German electrical apparatus to this country which are now ceasing. The demand from our manufacturers under the latter category may possibly be more or less automatic, although manufacturers—and also factors—will be well advised to have stocks ready for it when it comes; they know the home requirements, they should know full well the exact articles in which they have been defeated by German competition in the past, and they can start manufacturing for the supply at once. In the case of the foreign and colonial markets which have hitherto been buying German goods, however, the case is different. These are of the utmost importance to the manufacturer here and to the present and ultimate welfare of the country. It is reported already that agents from the United States are flocking to the Argentine to get American manufactures taken up in place of German ones, and Great Britain must lose no time in making similar moves in every country in which the previous German trade is worth acquiring.

Let us imagine a buyer, not necessarily in the Argentine Republic, but in Scandinavia, China or Japan, or even in our own dominions across the seas—Australia, British South Africa, or India—or possibly one in England itself; let us imagine this buyer receiving simultaneously one of the numerous circular letters sent out by our manufacturers saying that all quotations are cancelled and deliveries are not guaranteed, and a visit from an American salesman offering immediate execution of orders for any quantities of goods hitherto bought in Germany. Where will this buyer's order be placed? Incidentally, we strongly advise firms to discontinue these circular letters—which are in any

case redundant when a state of war exists—and to replace them with others commencing with the words, "We can supply . . ."

It is not merely to our manufacturers own interests to apply themselves with energy to find new outlets for trade; it is a patriotic duty. There may be a risk to their pockets both in keeping their works in full or nearly full activity, and in incurring increased expenses in connection with their selling organisation; it may be against every one of their business instincts to risk money on pioneer work when money is scarce and dear; but these are risks British manufacturers may well take in the name of patriotism. While men are risking their lives for their country, we at home may at least risk our money in the same cause and fight for Great Britain's supremacy as an industrial nation.

### THE EFFECT OF THE WAR ON THE ELECTRIC LAMP INDUSTRY

OF the industries in this country which will derive immediate benefit by the state of war in Europe, the incandescent electric lamp industry stands out prominently. Although there are no figures available as to the total number of lamps sold annually in the United Kingdom, a rough estimate given us from a well-informed quarter places it at about 12 million metal filament lamps and about 8 million carbon filament lamps. Of this total over 3 million metal filament lamps and about 1½ million carbon filament lamps were imported from Germany last year.

For the moment there may be a considerable drop in the demand, as dealers are nervous about buying in stocks, but this cannot continue long, and there is little reason to doubt that by the end of the year the consumption of lamps will be practically normal—and the 4½ million lamps per annum hitherto imported from Germany will have to be made in this country. This does not represent the total increase in the production, however, for Germany's export trade in lamps was by no means confined to Great Britain. Russia was a far larger customer; France, Switzerland, Italy, Spain, Scandinavia, and South America bought in very large numbers; British South Africa bought several hundred thousand, and the total number of lamps exported from Germany last year was between 50 and 60 millions. Except for the 5 or 6 million lamps sent to Austria, Great Britain should have an excellent chance in this large foreign and colonial market; her chief competitors will probably be the United States, France, and Holland.

Great Britain is already fairly well equipped to supply all her home demands for lamps and a large export trade as well. There are fifteen factories in this country making metal filament lamps. These works are of various sizes—some of them very large, others quite small—but their combined output when worked at their full capacity would probably be equal to the occasion. There are, however, some facts which modify the situation to some extent. Of all these works, two only blow their own bulbs, and the remainder have hitherto, we believe, imported all their bulbs—for the most part from Germany. The two works which possess the special glassworks for this purpose will probably be in a position to supply all the bulbs for their own increased output, but it is doubtful whether they would be able to supply bulbs to the remaining thirteen works. It will be necessary, therefore, for these works either to build the necessary glassworks themselves, or at any rate to take early steps to arrange for the supply of British-made globes. The glass-blowing industry—in fact, the glass industry generally—has been much neglected in Great Britain for many years, and we have come to rely on imports for a very large proportion of our requirements. It will probably be necessary to train glass-blowers, there-

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,405.

Two Chamberlain and Hookham ampere-hour meters, normally connected to read the "charge" and "discharge" current of a battery, were so connected that both meters read "discharge" current. This was done so that the "charge" meter (which accurately registered "charge" ampere-hours) could be used as a check on the "discharge" meter. But on comparing the two meter readings, the "charge" meter was found to be 18 per cent. slow, with the "discharge" meter. What is the explanation of this?—**DELTA.**

(Replies must be received not later than first post Thursday, August 27th.)

### QUESTION No. 1,404.

What are the main requirements to be kept in view in the design of brush holders for large multipolar machines?

Replies to this question will be published next week.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published August 13th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

25,659/13. **Improved Telephone Repeaters.** WESTERN ELECTRIC CO. This applies particularly to repeaters in which the incoming impulses are amplified by being allowed to excite an electromagnet, which in its turn acts upon the diaphragm of a microphone so as to produce large variations of current in the microphone circuit. The electromagnet is enclosed in a hollow metal tube, the top of which is enlarged to receive the microphone. The latter is so constructed as to be easily removable, so that another microphonic element, the diaphragm of which has a different period of vibration, can be easily inserted. This feature is of considerable value for wireless work. Five figures.

27,050/13. **Rivetting Machines.** SIEMENS & HALSKE AKT. GES. The main feature of this invention is the use of high-frequency current having a periodicity of about 500 cycles per sec. This current is supplied at normal pressure, e.g., 220 volts, and is transformed into a heavy current at low pressure. The use of high-frequency supply enables a small, easily handled transformer to be used. The secondary of the transformer consists of a stout copper tube, one end of which is in contact with the tool for forming the rivet head, the other end being connected through leads to the plates which are being rivetted. Three figures.

### Specifications Published To-Day

The following Patent Specifications will be published to day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Distributing Systems, Cables and Wires, Insulating Materials,** &c.: B.W.E.M. CO., LTD. (*Westinghouse Elect. & Mfg. Co.*) [Supports for overhead conductors] 11,309/14.

**Dynamos, Motors and Transformers:** SIEMENS BROS. DYNAMO WKS., LTD., and KIEFFER [Dynamo and motor windings] 18,907/13; FERGUSON and JOHNSTONE [Voltage and output regulators] 26,646/13; MENSFORTH [Commutators] 27,746/13; SIEMENS BROS. DYNAMO WKS., LTD. (*Siemens Schuckertwerke Ges.*) [Method of loading frequency converters] 2,408/14; [Starting rotary converters] 8,711/14; SIEMENS BROS. & CO. (*Siemens & Halske Akt. Ges.*) [Winding apparatus] 7,457/14.

**Incandescent Lamps:** SCHRADER [Hand lamps] 26,592/13.

**Instruments and Meters:** LANDIS & GYR GES. [Core for Ferraris meters] 17,480/13; NAT. ELECT. TIME CO. and SWIFT [Railway signalling] 20,684/13; A.E.G. [Watt-hour meter] 4,356/14.

**Switchgear, Fuses and Fittings:** BERRY and MARKHAM [Change-over switches] 16,840/13; [Combined switches and plugs] 16,841/13; AKT. GES. BROWN BOVERI ET CIE [H.T. oil switches] 17,583/13; DOUGHTY and GYTON [Pendant fittings] 21,193/13; MARKS (*Benjamin Elect. Mfg. Co.*) [Shade supports] 23,452/13; HEMMING [Conduit fittings] 26,764/13; SIEMENS BROS. and SCHUPP [Motor starters] 5,514/14, 8,889/14; R. BOSCH [Contacts] 7,685/14.

**Telephony and Telegraphy:** ERICSSON and DAHLSTRÖM [Telephone system] 17,038/13; SIEMENS & HALSKE AKT. GES. [Telephone systems] 17,417/13, 6,628/14; GALETTI [Wireless signalling] 17,859/13; MCGOWAN [Ear caps for telephoning] 22,485/13.

**Traction:** SIMS [Starting and lighting of road vehicles] 20,230/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos, Motors and Transformers:** LINCOLN [Synchronous booster rotary converters] 16,095/14.

**Electrometallurgy and Electrochemistry:** SCHOTT & GEN [Manufacture of electrodes] 16,063/14; MÖLLER [Separation of suspended bodies from insulating fluids] 17,175/14.

**Ignition:** LEDERER [Electric gas lamps] 17,036/14, 17,646/14.

**Switchgear, Fuses and Fittings:** SIEMENS SCHUCKERTWERKE GES. [Automatic cut-outs] 17,379/14.

**Telegraphy and Telephony:** MCGAURON [Telephone call recorders] 12,232/14, 12,233/14; LATOURT CIE [High-frequency alternators] 17,872/14.

**Traction:** SOC. ANON. DITE S.T.A.R. SYSTEME DE TRACTION AUTO REGULATEUR [Arrangements for motor control] 15,155/14.

The following Amended Specifications may now be obtained:—

**Traction:** F. C. V. DE CASTELLETO [Vehicle brakes] 9,274/13.

**Miscellaneous:** L. LAFFITTEAU [Sterilisation of liquids] 9,281/13, 9,282/13.

### Suspension of Patents

The Board of Trade has been empowered by Act of Parliament to do anything they think expedient for avoiding or suspending any Patent the proprietor of which is a subject of any State at war with his Majesty.

### Application for Amendment

5,210/09. **Ignition Devices.** SPARKING PLUG PATENTS, LTD., seek leave to the above Specification.

### Expiring and Expired Patents

The following Patent expires during the current week, after a **life of fourteen years**:—

14,875/00. **Fire Extinguishing.** J. F. H. GRONWALD. An apparatus for enabling the fire in a ship's hold to be rapidly located and extinguished. Outlet pipes, from each separate compartment of the hold, are led to the upper deck, and are provided with electric alarm thermometers, so that any hot smoke or gases escaping are immediately detected. Another set of pipes are led to a source of supply of some inert gas, e.g., carbon dioxide, which can thus be diverted into any part of the hold, either to extinguish the fire or to prevent any combustion of the cargo occurring. Three figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials,** &c.: B.T.-H. CO. (*G.E. Co., U.S.A.*) [Insulating compounds] 10,208/06.

**Incandescent Lamps:** WOLFRAM LAMPEN AKT. GES. [Metallic filament lamps] 8,416/08.

**Traction:** W. KÖHLER [Overhead collectors for trackless vehicles] 26,907/09.

**Miscellaneous:** P. T. SIEVERT [Apparatus for glass manufacture] 9,853/09; C. H. ROLLISON [Automatic balancing for aeroplanes] 10,299/09.

fore, in order to obtain a sufficient supply of skilled workmen, and an early start should be made.

Another interesting point is that practically none of the brass and vitrite caps of the lamps, so far as we know, are made in this country. The large majority of them come from Holland. This is, however, merely a question of price, and, if circumstances necessitated it, there should be no difficulty in making them here. We believe we are right in saying that a factory was established here, more or less as an experiment, a few years ago to manufacture lamp caps for several lamp-makers, but that it was discontinued as it was found that the foreign caps could be bought at a cheaper price owing to the very large production; for, strange as it may appear, Holland is said to supply lamp caps for the greater part of Europe's requirements. The manufacture of the filaments for metal filament lamps is another question. Several of the English lamp-manufacturers do not make the filaments themselves, but others do. In any case, there are probably sufficient stocks of tungsten or of the filaments themselves to tide over any difficulty of this sort; the question of patents will doubtless have some influence on the situation, but it may be assumed that patent rights will not be allowed to stand in the way of supplying the Country's requirements in lamps.

Before leaving the subject of incandescent lamps, a word may be said as to the half-watt lamp. It has been an open secret that the majority of the half-watt lamps obtainable in this country hitherto have been of German manufacture. Only one firm announces at present that it has a stock of British-made half-watt lamps immediately available. This firm will have a great advantage over its competitors, and it is reasonable to expect that others will follow suit and complete their arrangements for turning out sufficient quantities to meet the demand which will be a rapidly growing one. We may have more to say, in a later article, as to the causes which will contribute to this demand.

\* \* We hope to publish in successive issues further articles as to the effect of the war upon other branches of the electrical industry.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The present position of matters telegraphic may be briefly stated as follows:—The deferred and letter telegram services are suspended by all routes until further notice, except *via* the Atlantic Cable Companies and *via* Marconi, but even in these cases they are subject to exceptional delay and to the general restrictions announced in our previous issues.—The route to Germany by the lines of the Indo-European Telegraph Co. is entirely interrupted, and generally no messages can be accepted for Germany, Austria-Hungary, and Bosnia-Herzegovina.—The Belgian Government states that all telegrams to and from and in transit *via* Belgium must be in plain French, Flemish, or English, and must convey some intelligible meaning. Previous announcements of restrictions are still in force.—The Greek Government has suspended the use of wireless telegraphy on all ships in territorial waters.—All telegrams for the Union of South Africa are only accepted at senders' risk, and no applications for refunds will be considered, whether telegrams be stopped, delayed, or cancelled without notice to senders, or otherwise.—The Russian Government make a similar announcement.—The Austrian Administration confirms that all telegraphic relations with France and French possessions, Serbia, and Montenegro are suspended, including terminal as well as transit traffic.—Telegraphic correspondence with Great Britain and Belgium is entirely suspended.

The United States Government has established censorship over radio-telegraphic communication, and the Press states that this has never before arisen in a war, and that the action of President Wilson establishes a precedent. The

proclamation first confirms neutrality, and states that all radio-stations are hereby prohibited from transmitting or receiving for delivery messages of an unneutral nature, and from in any way rendering to anyone of the belligerents any unneutral service during the continuance of hostilities. There are, the *Sun* states, 200 or more public and Government wireless stations in the States, which are divided into nine districts. Some trouble is anticipated owing to the large number of amateur stations.

The Italian Government state that code and cipher is only admitted in Government and diplomatic messages, whether telegraphic or radio-telegraphic. Consular agents may send or receive messages in plain Italian, German, or French.—The French Government will no more accept telegrams with abbreviated addresses or signatures, nor telegrams having transited the German or Austro-Hungarian lines, or those of their Protectorates.—Telegrams to or *via* Roumania must be written in German, French, English, Italian, or Flemish.—The Tokio-Bonin cable is interrupted, and occurring at this time it may be well assumed that the cause is due to the estrangement between Japan and Germany, being a Japanese Government cable. It has, however, failed on a previous occasion through natural causes.

For some time a daily newsletter has been sent by wireless telegraphy from the Marconi station at Chelmsford to the *Algemeen Handelsblad*, in Amsterdam. The Dutch authorities were sceptical that this really arrived by wireless until they succeeded in picking up the message. The practice has been stopped as an infringement of the postal law.

### THE B.E.A.M.A. AND THE WAR

THE following letter has been sent by the chairman of the Council of the British Electrical and Allied Manufacturers' Association to the principal railways, corporations and other large purchasers of electrical plant and apparatus.

There are many evidences of a tendency on the part of purchasers (by no means the smallest) to take advantage of clauses in their contracts to suspend and delay work on account of the war; and the members of this Association, who employ tens of thousands of working men, are already so affected in respect of contracts representing over a million pounds sterling. Should such suspension and delay become at all the common practice, the result, for working men, would be disastrous. One of the primary duties of every Britisher at the present moment is to maintain employment as far as ever possible; and my Council desire to appeal for the prompt and sympathetic consideration of this question by all present or prospective purchasers of electrical goods and goods used in connection with electrical work. Our own Government, by common consent, has set an excellent example, financially and otherwise, and has given every assurance towards allaying traders' fears. The Colonial Governments have done the same, notably the Australian Government, who have publicly exhorted their own importers to keep up and extend trade with Britain, recognising at once the extremely important issue involved, both now and in the future. On behalf of the Council of this Association I commend this matter to your earnest consideration.

**War on German Trade.**—In view of the cessation of Germany's and Austria's overseas trade, the Colonial Office has telegraphed to some of the more important Colonies possessing responsible government to ask them for full information and samples of the principal imports to them from these countries. It is understood, also, that similar particulars from the Trade Commissioners in the various self-governing Colonies are also on their way to London, and the Foreign Office is sending a request for similar material to H.M. Consuls in some neutral foreign countries. When collected, the samples will probably be exhibited at the Imperial Institute. Although this information will undoubtedly be of some assistance to the electrical industry, our manufacturers should have already good knowledge of the details of the German electrical material sold abroad, and need not postpone their activities until the arrival of samples. In this connection, we refer our readers to the article headed "An Appeal to Manufacturers" on page 463 of this issue, and also to the detailed statistics of German exports published in our last issue. It is possible that the publication of these details—which were quoted by some leading daily newspapers—has assisted towards the action which the Government is now taking.

## "ELECTRICAL ENGINEERING" TRADE SECTION

### A MUNICIPAL SUB-STATION

THE Manchester Corporation have recently laid down a rotary-converter sub-station at the large carriage works of the Great Central Railway Co., in Manchester, to transform three-phase current at 6,600 volts 50 cycles to continuous current at 225 volts. The converting plant consists of three 300-kw. "Witton" rotary-converters, running at 750 r.p.m., and fed from a bank of three-phase oil-insulated, self-cooling transformers. The reactance method of voltage control is used, sufficient reactance being embodied in the

SUB-STATION AT G.C.R. CARRIAGE WORKS, MANCHESTER.

transformers. For starting, a slip-ring induction motor is carried on an extension of the shaft of each set with a three-phase liquid starter. The necessary synchronising gear is carried on a set of small panels between the starting motor and transformer. The General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, London, E.C.), were the contractors for the rotary-converters and control gear.

### A NEW TRACTION LAMP

A NEW form of traction lamp with a drawn-wire tungsten filament has been put on the market by Siemens Bros. Dynamo Works, Ltd. (Tyssen Street, Dalston). These are being

manufactured in England, and have spiralised filaments carried on spiders in the usual manner. Instead of the filament being wound up and down, as has been the case previously, the spider is arranged so that equal lengths of filament are carried vertically and horizontally. By this means neighbouring lengths of filament do not run parallel to each other, as with the existing method, which is liable to cause twisting or short-circuit of the filaments owing to vibration, but are set at right angles; and no bend is greater than a right angle. In practice, therefore, it is impossible to obtain a short-circuit, even under the most violent jars or vibration, and the lamp is equally strong when used in any position. The new arrangement accounts for a considerably increased spherical

WOTAN TRACTION LAMP.

candle-power, as the light given is practically uniform in all directions other than the cap end. The distance be-

tween the top and bottom supports of the spider is in no case greater than three-quarters of an inch, in order to provide the lamp with a mechanical supporting strength hitherto unobtainable, and it is practically impossible to break the filament or stem without breaking the glass of the bulb. Many exhaustive tests have been carried out on these lamps under severe artificial conditions of vibration, as well as on rolling-stock in use, and the results obtained lead to the belief that the longest possible average life will be obtained. The prices are the same as those of the previous Wotan traction lamps.

### SEARCHLIGHTS

WE illustrate here a pattern of wheel-house searchlight made by the London Electric Firm (George Street, Croydon), of which a number have just been completed for a large Scottish shipbuilder for use on passenger steamers. They are of the 20-in. size, constructed of brass throughout, and are fitted with high-grade silvered parabolic mirrors and diverging lenses. The firm have also developed another type for fire brigade purposes. These constitute a new development of searchlight work, and are for use in illuminating shadow-cast exteriors and dark interiors of buildings. They are extremely light, to enable them to be carried about easily, and very strong, to stand the rough work inevitable with such service. The lantern, which is arranged for tilting and swivelling, is carried on a tripod made to collapse by means of sliding members, and also to fold up, thus giving the maximum of advantage for transport purposes. A widely dispersed beam of light is produced, and the candle-power is given as 3,000.

PILOT HOUSE PATTERN OF SEARCHLIGHT.

### CORRESPONDENCE

MESSRS. A. P. LUNDBERG & SONS.

*To the Editor of ELECTRICAL ENGINEERING.*

SIR,—We should like an opportunity of correcting erroneous statements which have been made in various quarters to the effect that our stocks are dependent on Continental supplies, and that we act as "distributors" for German manufacturing firms.

The exact opposite is the case, for we have no factoring interests, and are essentially an English manufacturing firm.

Our business as manufacturers of electrical accessories was established in London over 32 years ago. Our Senior Partner is a naturalised Englishman of Swedish birth, whose home has been in this country for over 50 years. Our Junior Partners are both London born, the sympathies of the firm are entirely British, and our capital is all invested in this country.

Trusting that you will afford us this opportunity of removing an erroneous impression, which, unless the facts are stated, will prove detrimental to our interests.

We are, Sir,  
Yours faithfully,  
A. P. LUNDBERG & SONS.

London, August 13th, 1914.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**SWITCHGEAR.**—A new collection of leaflets from A. Reyrolle & Co., Ltd., Hebburn-on-Tyne, describe some recent additions to this firm's manufactures, including special dividing boxes for transformers, in which six leads are brought from the separate phase windings and mesh connections made inside the box, and a rotary pattern of isolating switch on cast-iron base with porcelain insulation. Other leaflets deal with quick-break switches, fuses, plug boxes, enclosed starters, and time-limit relays.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**QUICK-BOILING KETTLE.**—A leaflet just issued by the B.T.-H. Co. (Rugby) describes an electrically-heated kettle which is designed to meet the demand for a cheap and reliable article of this kind. The body is of copper, tinned on the inside to prevent corrosion, and the heating element consists of "calorite" metal ribbon wound upon a mica former. Two pints of cold water can be raised to boiling point in ten minutes with an energy consumption of  $\frac{3}{4}$  kw.

**STARTING COMPENSATORS.**—A further list from the same Company gives some interesting particulars of their starting compensators for squirrel-cage induction motors. The compensator consists essentially of an auto-transformer, which lowers the pressure across the motor terminals during the period of starting, which, by the way, should be about one minute. The use of these compensators reduces the rush of starting current, and also the starting torque, in proportion to the square of the reduction in voltage.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Dover.**—A sum of £1,000 is to be borrowed for services.

**Dublin.**—The Corporation has arranged to borrow £80,500 from the Bank of Ireland for the purpose of electrical extensions.

**Dundee.**—Rotary-converters and switchgear are required. General Manager. August 31st. (See an advertisement on another page.)

**London: L.C.C.**—Tenders are invited for the reconstruction of motor-generators in the tramway southern sub-stations. Clerk. September 8th. (See an advertisement on another page.)

**Minster.**—The question of providing an electricity generating plant for the Union is to be considered.

**Newport (Mon.).**—A loan of £16,000 is to be taken up for electrical extensions.

**Oldham.**—A storage battery, reversible booster and battery is required. Joint Electrical Engineer (Mr. F. L. Ogden). August 24th.

**Rochdale.**—Twelve months' supply of static transformers. Borough Electrical Engineer.

**Swinton.**—Alterations to the switchboard are required.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Birmingham.**—New school in Ryland Road, Erdington.

**Bristol.**—Public baths. Gloucester Road.

**Heywood.**—Extensions at Hope Mill.

**London.**—Charterhouse Telephone Exchange. H.M. Office of Works, Storey's Gate, S.W.

**Manchester.**—Alterations, Crumpsall Workhouse. Architect, A. J. Murgatroyd, 23 Strutt Street.—Public baths at Failsworth. Architects, Woodhouse & Howard.

**Wigan.**—Cinematograph theatre. P. Gaskell.

### Miscellaneous

**Belfast.**—An electric motor tower wagon is required by the Tramways and Electricity Department. City Electrical Engineer. August 24th.

**Brighton.**—Manganese steel tramway points and crossings. Tramway Manager. September 7th.

**Bury.**—Permanent-way and overhead equipment for  $1\frac{1}{2}$  mile of tramway. Tramway Manager.

**Peterborough.**—The Rural District Council is introducing electric pumping at their sewage works.

**South Wales.**—The Powell Duffryn Steam Coal Co. require a twelve months' supply of electrical stores. Particulars from Stores Manager, Aberaman, near Aberdare, and tenders to Company at 101 Leadenhall Street, London.

**Walthamstow.**—Tramway materials, including rails, castings, fish-plates, anchors, bolts, &c. Borough Surveyor. August 19th.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Although no official quotation is obtainable, the price of copper may be taken as from £70 to £72.

**Prices of Osram Lamps Unaltered.**—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), announce that, owing to the war, they have to withdraw all outstanding quotations and special terms, and that they may not be able to adhere to all guarantees and promises of delivery. All the Company's factories are still open, and every endeavour is being made to cause as little inconvenience as possible. The prices and conditions of sale of Osram lamps remain unchanged, but responsibility for damage in transit cannot be entertained.

**Agency.**—Fraser & Chalmers, Ltd. (Erith, Kent), have appointed Mr. H. A. Sturgess (The Oak, Motherwell) to represent them in Scotland.

**Crompton & Co.**—We are advised that Messrs. Crompton & Co. are very busy on Government orders, and are working night and day to expedite delivery, which is of national importance in the present crisis. Every effort, however, is being made to meet the requirements of customers in the most expeditious manner in the circumstances.

**Liquidation.**—A meeting of creditors of the National Electric Time Co. will be held at the offices of Messrs. Vincent & Goodrich, 9-10 Pancras Lane, E.C., on August 27th, at 3 p.m.

**Agency.**—The British Electrical Plant Co., Ltd. (Alloa, N.B.), have appointed Mr. Allen Williams (9 Queen Victoria Street, E.C.), as their agent in London and south of England. Mr. Williams also represents Eckstein, Heap & Co., Ltd. (Manchester), for switchgear, and The Anderston Foundry Co., Ltd. (Glasgow), for steam engines, air compressors, &c.

**Fittings.**—Nathan & Allen (Queen Anne's Chambers, Westminster), inform us that as their standard lanterns and fittings are of British manufacture (except a few special forms of glassware), they are independent of Germany, and, having good stocks of finished fittings and raw materials, are able to give their usual prompt despatch of orders. Prices will not be advanced unless absolutely necessary. They are preparing a catalogue of new designs, which will contain, amongst others, the "Orient Lantern," for half-watt lamps for shop-front lighting; an improved street-lighting fitting; semi-inverted "Opalba" bowl fittings; and a new semi-inverted fitting for half-watt lamps.

**The London Electric Firm.**—This firm inform us that they are carrying on as usual all their manufacture at George Street, Croydon, of lamp-lowering gear, &c., all of which is British made. Large stocks are in hand. Their searchlights (see page 466) are also entirely made at Croydon, and prompt deliveries can be guaranteed.

**Belgian Relief Fund.**—The Belgian Minister in London has opened a fund to relieve the distressed families of the Belgian soldiers now in the field, and to afford help to the sick and wounded. Contributions may be sent to the Belgian Legation, 15 West Halkin Street, S.W., or to Louis Godechaux, President of the Belgian Chamber of Commerce in London, 155 Fenchurch Street, E.C., marked "Belgian Relief Fund." All contributions will be acknowledged through the "Public Ledger."

**Meter Approved.** The Board of Trade has approved of a meter deposited on behalf of Messrs. C. H. W. Gerhardt, known as the "Met" single-phase alternating current 2-wire watt-hour meter Type T.O., and of the means for fixing same.

## LOCAL NOTES

**Bury St. Edmunds: Interruption of Supply.**—On Wednesday of last week a brief interruption of supply was produced which affected a portion of the public lighting, the Post Office, and surrounding district. The trouble was caused by a short-circuit on the network which threw out the circuit-breaker of the generator at work. A battery is in course of erection, which, had it been complete, would probably have prevented the interruption.

**Dover: Supply to Admiralty.**—An agreement is to be entered into with the Admiralty for five years for a supply of electrical energy for lighting and power on the following terms:—Lighting up to 50,000 units per annum (minimum 30,000), 3½d. per unit; between 50,000 and 100,000 units, 2½d. per unit; between 100,000 and 150,000 units, 1½d. per unit; above 150,000 units, 1d. per unit. Power:—Up to 20,000 units per annum 2½d. per unit; over 20,000 units, 2d. per unit.

**Great Harwood: Electric Lighting.**—The revocation of the electric lighting Order, which should ordinarily expire this month, has been postponed for twelve months by the Board of Trade.

**King's Lynn: Electricity Accounts.**—The accounts of the Electrical Department for the year to March 31st, 1914, show a balance of £4,663 carried to net revenue account. The balance carried forward for the previous year was £2,388, and after meeting capital charges and allocating £257 towards expenditure on meters and mains, the net revenue account shows a balance of £3,908. The total number of units sold was 669,874, against 559,647 in the previous year. The load factor improved slightly from 16·42 per cent. to 16·99 per cent.

**Portsmouth: Electricity Profits.**—There was a net profit of £3,342 upon the electricity undertaking last year. The Corporation has decided to allocate a good portion of this to relief of rates.

**Springhead: Electric Supply.**—The Council, jointly with the Lees Urban District Council, is asking the Oldham Corporation to obtain an electric lighting Provisional Order for these two districts.

## THE PRINCE OF WALES' NATIONAL RELIEF FUND

PERSONS in all walks of life in this country will have read the special appeal by the Prince of Wales for funds to be used for the relief of the distress caused by the war among those least able to bear it, and we cannot doubt that our readers will be liberal in their response. In order to assist them in the performance of this national duty we give the coupon below, which may be used for forwarding contributions of any magnitude. Needless to say, the smallest contributions will be as gratefully received as those from subscribers of large means.

I enclose £      s.      d. towards the Prince of Wales'

### NATIONAL RELIEF FUND

Name .....

Address .....

This coupon should be filled in, and the envelope, which need not be stamped, addressed to H.R.H. The Prince of Wales, Buckingham Palace, London.

## APPOINTMENTS AND PERSONAL NOTES

Having regard to the present state of affairs, proposals to increase the salaries of Mr. N. Appelbee and Mr. Holt, Electrical Engineer and Tramway Manager respectively at Ashton-under-Lyne, were withdrawn at a meeting of the Council last week.

Mr. Charles Furness, Electrical Engineer and Tramways Manager to the Blackpool Corporation, left on August 12th for Eysden, Holland, near the Belgian border, to bring home his fourteen-year-old daughter, who was at school there. We are pleased to hear that Mr. Furness has arrived safely back with his daughter.

Mr. Dunlop, Secretary of the B.E.A.M.A., who was in Zurich when the war broke out, has now returned to London. He left Zurich on Wednesday last week, and only arrived in Paris at noon on Saturday. The journey from Zurich to Geneva took a day and a half, and a like time was occupied between Geneva and Paris, both under extremely uncomfortable conditions.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**W. T. Henley's Telegraph Works Co.**—An interim dividend at the rate of 10 per cent. per annum, free of tax, is declared upon the ordinary shares for the June half-year.

**South Metropolitan Electric Light & Power Co.**—The usual interim dividends are announced upon the seven per cent. cumulative first preference shares and the six per cent. cumulative second preference shares.

**Tyneside Electrical Development Co.**—An interim dividend of 5 per cent. is declared.

**Waste Heat & Gas Electrical Generating Stations.** An interim dividend of 2½ per cent. is announced.

**Bournemouth and Poole Electricity Supply Co.**—A circular has been sent to the ordinary shareholders expressing the directors' opinion that it is advisable, in view of the present financial conditions, to conserve the cash resources of the company. It is therefore proposed to postpone the payment of their interim dividend on the ordinary shares announced on July 9th.

**A "Run" on Electric Vehicles.**—Owing to so many horses having been commandeered for Army purposes, it is stated that large tradesmen in London and elsewhere have been hard put to keep pace with their deliveries. Many petrol motor lorries are also being requisitioned by the war authorities. It is not surprising, therefore, that all the small stock of electric commercial vehicles has already been bought up, and the prospects are encouraging for an extension of the manufacture of electric vehicle chassis; there should be no difficulty in obtaining the necessary batteries.

Edison Accumulators, Ltd., have even sold all their demonstration cars, and have urgent orders from present users for further vehicles. Similarly, the Torpedo Electric Motor Co. has sold all its stock of vehicles, and Messrs. Mossay inform us that had they had in stock another two dozen vehicles they could have sold them. All this has happened since the declaration of war. The agent in this country for the French-made F.R.A.M. vehicles was expecting a batch over from France towards the end of the present month, but there are doubts whether these will be delivered for some little while now.

**Electric Light Switching Examination.**—Following is a complete list of successful overseas competitors in the last examination in electric-light switching conducted by Messrs. A. P. Lundberg & Sons (Liverpool Road, N.).—*Advanced Grade*:—A. W. Honychurch, Christchurch, Barbados, West Indies; H. S. Tiley, Potchefstroom, South Africa. *Intermediate Grade*:—H. R. Constantine, Zug, Switzerland; R. Drilhon, Pau, France. *Preliminary Grade*:—H. Cristall, London, Ontario, Canada; A. K. Dass, Delhi, India. The next examination will be held in November, in connection with ELECTRICAL ENGINEERING, as our readers may remember.

Telephone No.: 5509 Holborn

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

FURTHER particulars are given of electrical employees serving with the Army and Navy. (Page 469.)

WE publish further particulars of the prospects of electrical trade in various countries in which Germany has hitherto occupied the market to better effect than Great Britain, and these, taken in conjunction with the details of German export trade published in our issue of August 13th, will doubtless be useful to manufacturers. (Page 470.)

THE threatened shortage of carbons will be averted so far as flame arc lamps are concerned. We give a review of the situation, and publish an important letter on the subject from the General Electric Co. (Page 470.)

THE French Government are allowing the fee usually payable on application for patents to be deferred till after the war. (Page 471.)

THE design of brush holders for large multipolar machines is discussed in our Questions and Answers columns. (Page 472.)

THE Institution of Electrical Engineers has a register of men willing to assist in the maintenance of electric supply and other public services. (Page 472.)

NOTES on the arrangements for the next session at some of the Universities and Technical Colleges are given on page 472.

A CONSIDERABLE number of contracts for tramway rails and tyres which had been placed abroad are now likely to pass to British firms.—The Conference of the Municipal Tramways Association has been cancelled.—Electric traction was dealt with in a Paper by Prof. W. E. Dalby at the Australian meeting of the British Association. (Page 473.)

A PAPER on the capacity of wireless telegraph aerials was read by Prof. G. W. O. Howe at the British Association.—Notes are given on the further restrictions in telegraphic communication on account of the war. (Page 473.)

AN improved method of wireless signalling, the manufacture of conduit fittings, and a device for starting rotary-converters, were contained in some of the Specifications published last week.—Opposition has been entered to the grant of a Patent for an improved magneto. (Page 474.)

THE regulations dealing with applications for suspending British patents granted to Germans and Austrians are given. (Page 474.)

OUR Trade Section contains articles on a glass works for the manufacture of lamp bulbs, and some new enclosed switches, &c. (Pages 475 and 476.)

CABLE is required at Liverpool and Wimbledon; a private generating plant at Bradford; electric lighting fittings at Torpoint; plant extensions at St. Pancras and Colwyn Bay; telephone apparatus in Australia, and tramway extensions at Leeds. (Page 476.)

THE importance of showrooms and wiring powers are referred to in the annual report of the South Shields Borough Electrical Engineer.—The Diesel engine supplied to the Wallasey Corporation is to be taken back by the contractors.—The Tasmanian Hydro-Electric Power Co. is to be purchased by the Government. (Page 477.)

## ELECTRICAL EMPLOYEES WITH THE ARMY

WE give some further information with regard to electrical employees who are now serving with the Army and Navy and Territorial Forces.

*Western Electric Co.*—39 men have been called to the Reserves, and 62 to the Territorials.

*St. Marylebone Borough Council, Electricity Department.*—21 members of the staff have been called up and probably four others will join shortly. The Council has decided to reinstate all men so affected, and to pay the difference between ordinary wages and the Army pay.

*Brighton Corporation, Electricity Department.*—35 men. This is a very considerable percentage of the staff, but Mr. J. Christie, the Borough Electrical Engineer, informs us that he has been able to make arrangements to carry on in their absence and that all posts will be kept open. The Council will pay either half wages or make the amounts received by dependents what it was in normal time.

## OPENINGS FOR THE EXTENSION OF OUR ELECTRICAL EXPORT TRADE \*

THE Board of Trade have issued an interesting and useful pamphlet to assist electrical manufacturers in making the immediate attack on foreign and colonial markets recommended in our issues of August 13th. The publication commences with some extracts from German trade statistics as to their exports; we do not quote these in full as they are not quite so complete in all respects as those published in our issue of August 13th, and apply to the year 1912, whereas ours were actual figures for last year. The general conclusion is the same, however; there is an enormous amount of trade to be obtained by individual energetic action in the countries which have hitherto been buying German electrical goods. If we were to obtain all the German electrical trade in electrical machinery in British South Africa, Australia, Russia, Norway, Holland, France, Spain, Italy, Greece, Roumania, Bulgaria, Turkey, Japan, Argentine, Brazil, Chile, Uruguay, and Mexico, which are the principal German markets, we should treble our exports to these countries; in 1912 Germany and Austria sent £2,583,000 worth of dynamos, motors, and transformers there, as against Great Britain's export to the same countries in 1913 of £1,336,100 of electrical machinery.

Some detailed figures of Austria's exports are given in the Board of Trade returns, but the totals are but a fraction of Germany's, and the markets are practically the same.

The chief value of the present paper issued by the Board of Trade is in the interesting collection of extracts from reports emanating from Trade Commissioners and Consuls during the past year or so, which when read now give clear indications as to how we can profit by the new conditions.

**South Africa.**—The following tabular statement gives imports into South Africa during 1913:—

	From the U.K.	From Germany.	From Austria.
Cables and Wires ... ..	£170,000	£71,000	£2,000
Fittings, including posts ...	£155,000	£67,000	£1,000
Electrical machinery ... ..	£142,000	£253,000	—
Telegraph and telephone material	£10,000	£1,000	—
Tramway rails ... ..	£2,000	£14,000	—
Tramway rolling stock ... ..	£16,000	£1,000	—

The magnitude of the electrical trade in South Africa can be gauged by the fact that the imports of electrical goods during the last six years have amounted to £6,000,000. It is stated that latterly trouble with some of the foreign-made plant has occurred "to an alarming extent," and that faults have developed due not only to over-rating, but also, in some cases, to bad design and manufacture. One reason why foreign firms have been more successful than British firms is that they have carried good stocks and have not kept the mines waiting for deliveries. At present the chief opportunity for British manufacturers of heavy machinery will only be for extensions and renewals of existing plants. Makers are advised not to rate their switches and circuit-breakers too high, as they are apt to be overloaded, and it is said that in the case of smaller switchgear mechanical strength is often neglected. Germany in 1912 supplied about 70 per cent. of the three-phase motors, generators, and accessories, Great Britain 20 per cent., and the United States 10 per cent., so that with proper representation and readiness to supply promptly, the German trade should go to us rather than to the United States. The supply of lamps has been practically entirely in the hands of German manufacturers. In 80 per cent. of the electric winding plants erected, the electrical portion is of German manufacture, although Great Britain supplies the bulk of the mechanical portion. Electrically-driven air-compressing plant is divided among British, German, and American manufacturers in the approximate proportion of 30, 60, and 10 per cent. respectively; practically all air-compressors are electrically driven. Referring to rock drills, the report says: "An electric rock drill of absolutely reliable and simple construction would be greatly appreciated, but nothing of this type has proved practical." In Port Elizabeth, Germany's electrical imports in 1912 were large, but only second to Great Britain except in the case of electric lamps. Lamps with B.C. caps are used.

(To be continued.)

## EFFECT OF THE WAR ON STREET LIGHTING

A DANGER which has been realised by many electrical engineers, ever since the German and Austrian mobilisation began, is that it might become increasingly difficult to maintain the lighting of our streets by arc lamps. Practically all the carbons which have been used in these lamps are imported from Germany and Austria. There is one carbon factory in this country—that of the General Electric Co., of which we shall have more to say presently—capable of supplying from 10 to 15 per cent. of the total carbons used; there are small factories in Spain (the Compañía Fabril de Carbones Electricos of Barcelona), in France (Fabrius Henrion of Nancy), in Switzerland (the Elektrocarbon A.-G. of Zurich—formerly G. A. Pestalozzi and Co.), and a large carbon works in the United States (the National Carbon Company, Cleveland). None of the foreign works, however, will be in a position to send any large quantities of carbons to this country, as they have their own countries' requirements to supply; Switzerland and the United States have been supplementing their own production with large purchases from Germany and Austria; the Spanish company can, in any event, send comparatively few carbons over here, and the French company's works at Pagny-sur-Moselle are situated almost in the midst of the present military operations on the French frontier.

It will be seen, however, that arrangements are being made—but with some difficulty—to prevent a carbon famine, and at any rate to keep going the portion of our public street lighting which is supplied by the more modern flame arc lamps. The use of the older open-type arc lamps will perhaps be no longer possible as stocks of carbon run out, but in any case they would be superseded either by flame arc lamps or metallic filament incandescent lamps in the course of time.

The General Electric Company's carbon works were started some twelve years ago, but have always been run at a considerable loss, as they were unable to compete with the lower-priced foreign carbons. We believe we are right in saying that not a single electric lighting authority (either municipal or company) and but one out of all the railways companies have been using British-made carbons for several years. With patriotism and foresight, the carbon works have, however, been kept in operation, and at the present juncture are the only works upon which the Admiralty have had to depend to maintain a sufficient stock of carbons for the searchlights. Since the outbreak of the war, they have been at work night and day practically manufacturing only for the Admiralty, but now apparently they are able to turn their attention to supplying the needs of the railways and electricity supply authorities for street lighting. The letter from the company, which we publish below, shows that the supply of flame arc lamp carbons will, as we have said, be maintained; supplies for purposes for which there is no urgency, and the hoarding up of stocks will be prevented by keeping up prices. They will also make other types of carbons to a limited extent, and will also make suitable carbons for cinematograph theatres. The last-mentioned might be deemed unnecessary, but a simple manufacturing expedient renders it possible; the carbons used for cinematograph lamps are of the same material as those for searchlights, but of smaller diameter, and the "throw-outs" in manufacture can therefore be cut down and utilised.

In the present crisis the General Electric Company have acted in a thoroughly public-spirited manner. They approached the Board of Trade almost immediately after the outbreak of the war, suggesting that the Board should establish an independent authority for the purpose of distributing the output from the carbon works and the various stocks held in the country to the best advantage, and offering them the output

\* Previous articles, "Germany's £14,500 Export Trade Analysed," "An Appeal to Manufacturers," and "The Effect of the War on the Electric Lamp Industry," appeared in our issues of August 13th and 20th.

of the works for this purpose. This offer was, however, not accepted by the Board of Trade, who, however, immediately took the step of urging the electricity supply authorities to economise their carbons and to replace arc lighting by other forms of lighting, wherever possible. Such measures will, it may be hoped, only now be necessary in isolated cases.

The letter which we have received from the General Electric Company is as follows:—

*To the Editor of ELECTRICAL ENGINEERING.*

SIR,—As it is impossible for us to explain the position in the arc lamp carbon industry individually to all inquirers and users, we should be glad of the hospitality of your columns for this purpose.

Our carbon works is the only factory in Great Britain, and the enormous preponderance—approximately nine-tenths—of the carbons used in this country have been imported from abroad from factories in Germany, Austria, and France, which for some time to come cannot send supplies. A very small percentage of the carbons imported came from small Swiss and Spanish works, who can do little, if anything, to relieve the situation. A factory exists in the United States, but will be called upon to make up for the large American demand hitherto supplied by Germany. In addition, it must be remembered that the British Dominions have been large buyers of German-made carbons.

Under the now prevailing circumstances, we have not been surprised, during the last three weeks, to receive enormous demands for carbons for both immediate and forward delivery. In less than a week we could have sold our output a year ahead. A few of these inquiries come from our old customers; the majority from the large users, such as railway companies and municipalities, who have consistently refused us their support in the past, on account of the cheaper prices of German and Austrian carbons. Our endeavours to educate users to the necessity of supporting the only English works with only a small portion of their requirements have been constant for 12 years, but without practical results.

When our works were started 12 years ago the prices ruling for carbons were about double those recently prevalent in this country. The starting of our works was met by a persistent policy of price-cutting on the part of our competitors, which at once made the factory unremunerative. In spite of this we have kept our works running, because we recognised the possible disaster if this country had not at least one source of home supply. This policy has involved our company in a loss amounting to over £70,000, which has naturally not encouraged us to increase the factory to a size capable of supplying a reasonable share of the English demand.

We are, therefore, now faced with a demand some ten times as great as we can satisfy. After serious consideration, we have decided to act upon the following principles:—

(1) In the first place, we shall of course supply all Naval and Military demands.

(2) We have raised prices, not merely to a remunerative level, but sufficiently to prevent buying by those who are not in absolute need. In this connection, we realise that it is possible for many of the largest users to replace temporarily their arc lamps by other forms of lighting, such as metal filament lamps, and those who are in this position should be encouraged to do so.

(3) We shall dispose of our present stock of carbons of all kinds according to the above principles, but as far as manufacture is concerned we shall adhere to the programme described below.

(4) We propose to limit our manufacture to as few types and sizes as possible in order to obtain the maximum output from our existing works.

We would point out in this connection that by reducing the number of sizes we make, our output can be very materially increased, as the machinery can be utilised to the best advantage.

In deciding what sizes we shall make, we have been principally guided by the consideration of what types of arc lamps can best be replaced by other forms of illuminants, and as far as possible we are therefore confining our manufacture principally to those types of arc lamps which in our opinion cannot easily be replaced.

We propose, therefore, in the first place to make carbons for magazine flame lamps—as there are many thousands of such lamps in use of two or three well-known makes using the same sizes of carbons. Subject, of course, to possible Government requirements our output of these magazine carbons should be sufficient to meet all demands. These carbons are 9 mm., 8 mm., and 7 mm. in diameter in 15 in. and 12 in. lengths. Similar carbons with the addition of 10 mm. diameter—if provided with metal cores—can be used in these lengths in practically all converging carbon flame lamps.

Secondly, we shall manufacture a certain quantity of 11 mm. and 13 mm. enclosed lamp carbons in 12 in. and 10 in. lengths, as enclosed lamps are used for certain purposes for which other sources of lighting are not suitable.

Thirdly, we propose to make a certain quantity of carbons for projection work for cinematograph and similar purposes, where the quantities are comparatively small, and where also any other source of light is inadmissible. The stoppage of these supplies would paralyse the whole trade, and cause very great distress.

As we realise that the amount of open type carbons which we could by any means produce would be a mere drop in the ocean, we shall discontinue for the time being the manufacture of these entirely.

We are confident that, in taking this course, we are acting in the best interest of carbon users and the public generally, and hope our policy will meet with general support. Individuals will realise that, where it is absolutely impossible to satisfy all, we are taking a course which enables us to satisfy the greatest number in our power.

Yours faithfully,

For and on behalf of the General Electric Co., Ltd.,  
K. ALWOOD (Secretary).

The position of some of the electricity undertakings with regard to carbons is as follows:—

*Birmingham.*—There is some difficulty in getting satisfactory supplies, but there are enough to carry on for the next four months.

*Bristol.*—The carbon stock is quite satisfactory, as in accordance with the Board of Trade suggestion special economies have been introduced which will obviate any serious risk of interference with arc lighting at any rate for several months.

*Dublin.*—Alternate street arc lamps are extinguished after 11.30 p.m.

*Cardiff.*—During the past two years clusters of metal filament lamps have been substituted for nearly 700 old arc lamps, and a stock of old carbons has been offered to the Government authorities. Should they not require them, consumers with arc lamps of a similar type will have the next refusal, and the remainder will be sold at cost price to anybody else to whom they would be useful.

*Derby.*—There are about 200 street arcs and 100 shop arcs on maintenance contract. The street arcs are now trimmed daily with carbon ends, and they are changing over to 500-watt half-watt lamps on all parallel circuits. They have a fair stock of half-watt and one-watt lamps, and will continue the change over as necessity arises.

*Blackpool.*—There is sufficient stock of carbons to maintain public lighting under normal conditions for nine months, and by certain economies if necessary for twelve or eighteen months.

*Glasgow.*—Two months' supply of carbons is in stock.

*East Ham.*—Besides general economies, preparations are being made for replacing street arc lamps with ordinary metal filament lamps should the emergency arise.

*Shoreditch.*—There are sufficient stocks to go on for a considerable time.

*Islington.*—Consumers with arc lamps are being offered the short ends of carbons which have been used for street lighting, at a nominal price.

In closing this article, it may be mentioned that the position with regard to incandescent gas lighting is, if anything, more serious than that of arc-lamp lighting, as the large proportion of the gas mantles used have come from Germany, and it will probably be even more difficult to obtain gas mantles of large candle-power than it is to obtain arc-lamp carbons.

## THE WAR AND FRENCH PATENTS

WE are informed by Mr. W. H. Taylor (author of the "Inventor's and Patentee's Year-Book") that he learns from his Parisian agent that by a decree given on the 16th inst. the French Government, with commendable thoughtfulness for inventors, will allow applications for patents to be made without payment of the usual application fee of 100 francs. Such payment is only to be made after the war, and on a date to be subsequently fixed. The decree applies to British applicants, and presumably to all others except subjects of those countries at war with France.

**The British Association.**—The address of Professor E. G. Coker, President of Section G (Engineering) of the British Association, given at Sydney on last Friday, dealt with the distribution of stress in materials and modern methods of its experimental determination, including the examination by polarised light of stressed models of transparent material, a subject which Professor Coker has made particularly his own.

**The Prince of Wales's Fund.**—The General Electric Co. has contributed £500 to the Prince of Wales's Fund.—The directors of the Newcastle-upon-Tyne Electric Supply Co. and the County of Durham Electrical Power Distribution Co. have made a first contribution of £300 to be administered in the Companies' areas of supply.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

*Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.*

### QUESTION No. 1,406.

Several D.C. compound-wound, 230-volt generators, varying in size from 250 to 750 kw., run in parallel on the bus bars to supply works' load, all series windings being connected to an equaliser bus bar. There is a shortage of power, and it is desired to make use of a 1,150-kw. 460-volt compound-wound interpole generator. Could this machine be made to run in parallel on the 230-volt bus bars, and, if so, what current can be taken from it? State what alterations, if any, will have to be made.—"DOUBTFUL."

*(Replies must be received not later than first post, Sept. 3rd.)*

### ANSWERS TO No. 1,404.

What are the main requirements to be kept in view in the design of brush holders for large multipolar machines?

The first award (10s.) is made to "KOIL" for the following reply:—

The following points should receive proper consideration when designing brush holders. In addition to these there are the questions of adjustment of brush position (rocking), insulation of brush bars, and supporting of same, &c., all of which come under the heading of cross-bar rather than brush holder design. A thoroughly good brush holder should comply with the following conditions:—

(1) Rigid construction—to prevent any vibration being set up in brush-box or cross-bar.

(2) Pressure adjustment—to ensure proper contact between brush and commutator, and to enable compensation for wear to be obtained.

(3) Position adjustment—to ensure the brush bedding on the commutator at the correct angle, even when this latter has worn down to its minimum permissible diameter.

(4) Flexible copper connection to join brush and brush-box (held by a mechanical clip at each end) to prevent heating due to faulty connection between these parts.

(5) Moving parts to have low inertia—to enable the brush to follow as rapidly as possible any inequalities on the commutator periphery.

(6) Brushes as short (axially) as possible—to limit the influence of a bad part of the commutator to as small a proportion of the whole brush area as possible.

(7) Staggering of brushes—to prevent grooving of the commutator.

(8) Brushes to be removable for inspection when the machine is running.

(9) The brush holder to be removable without the others being interfered with.

(10) Brush-box to be sufficiently large to prevent the brush sticking when expanded through heat, and to ensure that the brush will not rock owing to the radial part (which envelops the brush) being too narrow.

The second award (5s.) is made to "S. N.," who writes as follows:—

The main requirements to be kept in view in the design

of brush holder for large multipolar machines may be summarised as follows:—

(1) Brushes on each brush stud to be independent, to allow for the removal of any one brush while the machine is running, the remaining brushes being of sufficient size to carry the current, while one is removed for inspection or renewal.

(2) Positive connection from the brush to the brush holder so as not to rely on the surface contact between them.

(3) A minimum width axially to the commutator to be taken up by mechanical arrangement so as to utilise, as far as possible, the whole width of the commutator.

(4) The pressure springs should exert constant pressure throughout the life of the brush, and the pressure should be easily adjustable.

(5) For the sliding brush type of holder the inside of the boxes should be smooth and straight, the brushes being a good fit to prevent chattering and movement in the box, which would prevent good bedding, and at the same time be quite free to slide.

(6) The brushes should be fed as near radially as possible: a slight rake may, however, be given in the direction of rotation, as this is found to counteract tendency to chatter.

The use of solder for the connecting lead or "pig-tail" to the brush should be avoided; either a metal clip should be used or the strands of the flexible worked into the substance of the brush during manufacture. (3) gives an argument in favour of casting all the brush holders in one piece, the space between brushes being thereby lessened; this, of course, applies to the sliding brush type, and this method of manufacture scores over stamped brush-boxes under (5), the use of modern methods of casting giving a good inside finish without further tooling. The condition of (4) is best met by helical springs, which should be as long as possible. Another point which might be mentioned is that no small or vital parts should occur at parts at which an arc-over would strike the holders; the metal here should be heavy, so that no material damage would be done in such a case; the complete holder should be as short as possible circumferentially to the commutator, in order to guard against this trouble.

## NATIONAL SERVICE

THE Institution of Electrical Engineers has received offers of service from some 1,100 members and others, in response to the circular sent out recently which was referred to in ELECTRICAL ENGINEERING, August 13th, p. 457. A circular letter is being sent to engineers of all the electric supply undertakings in the United Kingdom stating that a large number of electrical engineers have offered their services (subject to various periods of notice) to fill vacancies in connection with the public services, electric power stations, tramways, railways, &c. These names have been classified by means of index cards under various headings, and are at the disposal of supply undertakings should any of the men's services be required.

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

The next session of the University of Edinburgh commences on October 13th. The three years' courses in electrical engineering qualify for the degree of B.Sc.

Three and four year courses in electrical engineering are given at the Royal Technical College, Glasgow, which is affiliated to the University. Special instruction is given in wireless telegraphy.

The report of the Council of the City and Guilds of London Institute contains the reports and accounts relating to the work of the City and Guilds (Engineering) College, South Kensington, and of the City and Guilds Technical College, Finsbury, for the last session. In addition to statistical matter, &c., connected with the various courses, some interesting notes are given on the activities of old students.

In view of the large withdrawal of engineering students from Continental colleges and works on account of the war, the Governors of Faraday House Electrical Engineering College are willing to offer special arrangements to those who wish to join the College. They are prepared to take into consideration as far as possible the time already spent abroad, and to shorten proportionately the four years' course ordinarily required for the diploma. Students would complete their practical training in large engineering works and power stations in the United Kingdom.

The next term at the Crystal Palace School of Practical Engineering will commence on September 9th. Particulars of the course at this Institution, of which the Principal is Mr. J. W. Wilson, can be obtained from the Registrar.

## ELECTRIC TRACTION NOTES

The iron and steel industry will be able to pick up some large orders in this country on account of the war, as there are contracts for rails and tyres let to German and Belgium firms which it will not be possible to execute. One of these, for instance, is a contract for 6,000 driving-wheel tyres and 4,000 pony-wheel tyres let by the London County Council last July to Messrs. John Batt & Co., who are agents for the Vereinigte Stahlwerke van der Zypen und Wissener Eisenhütten A.G. of Cologne. The contract has not been cancelled, and we understand that Messrs. Batt & Co. are endeavouring to find a British firm to take it over as sub-contractors. Meantime, however, the L.C.C. have ordered the same quantity of tyres, which represents a six months' supply, from Messrs. H. Bessemer & Co., whose tender in July had been the next lowest.

It is anticipated that it will be possible to inaugurate "through" electric train services between the Elephant & Castle and Watford by the end of this year. This will be the first portion of the intercommunication scheme with the London underground railways made possible by the electrification of the London & North-Western suburban lines.

It has been decided to cancel all arrangements for the Annual Conference of the Municipal Tramways Association, which was to have been held at Salford in September. The Council felt it inadvisable to hold the Conference in the present circumstances.

Among the Papers read before the Engineering Section at the British Association meeting in Australia was one on "Railways and Motive Power," by Prof. W. E. Dalby, F.R.S. Various curves relating to the development and cost of working of English railways were shown. The question of motive-power was considered and the advantages of the locomotive and the electric motor compared. Curves were also shown illustrating the proportion of fuel actually used to draw a train, as compared with the quantity fired in the furnace of a steam locomotive and in the furnace of a central station in the case of electric traction. Other curves illustrated the limits of economy and speed of a steam locomotive and the electric motor compared together in relation to special problems in connection with suburban traffic.

The Directors of the Oldham, Ashton & Hyde Electric Tramways, Ltd., have decided to postpone the interim dividend on the ordinary shares, owing to the war. In ordinary circumstances it would have been paid on August 15th.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The Italian Administration states that plain English is now authorised for telegrams or radio-telegrams for Consular agents.—The Argentine Republic has suspended telegrams in code. This does not apply to Government and Consular telegrams.—The cable between the French Penal Settlement of New Caledonia and Australia was interrupted on the 20th inst.—Since the 21st inst. communication with Brussels has been entirely cut off, and telegrams cannot be accepted for the Provinces Limburg, Liège, Namur, Luxemburg, Brabant, or Antwerp, excepting the town of Antwerp.—The Egyptian Administration only now accepts terminal and transit telegrams at senders' risk. They must be in plain English, French, Arabic, or Turkish, fully addressed and signed.—The Japanese Government notify following restrictions on terminal and transit telegrams: Private telegrams originating in Japan must be in plain Japanese, English, or French; but code telegrams are accepted at Tokio, Yokohama, Osaka, Kobe, Nagoya, Yokkaichi, Simoneseki, Nagasaki, Moji, Sapporo, Hakodate, and Otaxu under certain restrictions..

Telegrams for Ghent may be accepted.—The cable between Tokio and the Bonin Islands was repaired on the 23rd inst.—The Belgian Army, it is believed, blew up the wireless station at Laeken before evacuating Brussels.—The Shanghai-Nagasaki cable is reported to be down, and the wireless station at Tuckerton closed by the American Government.

Among the Papers read before the Engineering Section of the British Association in Australia was one on "The Capacity of Radio-Telegraphic Aerials," by Professor G. W. O. Howe. The capacity considered in this Paper is the actual static

capacity, and not the equivalent capacity of the antenna considered as part of an oscillatory circuit. The accurate calculation of the capacity of a multiple-wire horizontal aerial with its leading-down wires would be a difficult mathematical problem, quite unwarranted by the practical requirements of radio-telegraphy. When raised to a potential above or below that of the earth, the charge is distributed over the antenna in a way which is not easy to calculate, but which must be such that all parts of the antenna are at the same potential. If the antenna were made up of a great number of short pieces, placed end to end, but insulated from each other, it would be possible to distribute the charge uniformly, but the potential would then vary from point to point in a way which is easily calculated. If now we assume that all the separate pieces of wire are connected, electricity will flow from points of high to points of low potential until the potential is everywhere the same. The assumption made in developing the various formulæ is that this final uniform potential is equal to the average value of the potential when the charge was uniformly distributed. This is only approximately correct, but the accuracy is more than sufficient for all practical purposes. This method has been applied to antennæ of all the types usually employed, and formulæ have been established for each type. A large number of numerical examples have been worked out, and the results are given in tables and curves, so that the capacity of any antenna can be read off directly from its dimensions. The corrections due to the leading-down wires and to the proximity of the earth are fully considered, and examples given showing the application of the formulæ to antennæ of any type.

An interim report of the Committee on Radio-telegraphic Investigations was submitted to Section A, dealing with the arrangements made for the collection of statistics and the proposed observations during the solar eclipse. This work was of course, entirely suspended owing to the war.

Three wireless telegraph stations are being erected in Hudson Bay and the Straits to facilitate shipping. These will provide a continuous line of communication with the Atlantic.

A new wireless station is being erected by the Canadian Government at Cape Race, with a radius of 500 miles.

During a recent voyage of the Canadian Northern R.M.S. *Royal George* interesting tests were made of the Marconi-Bellini-Tosi wireless compass, the installation of which we have already announced. The instrument is stated to have been accurate within one degree in determining the compass direction both of shore stations and stations on other vessels. They had, for instance, been able to ascertain the compass position of Cape Race, Cape Ray, Father Point, and verified wireless signal direction from the s.s. *Columbia*, the s.s. *Calgarian*, and the s.s. *Sicilian*. The *Columbia* was sixty-eight miles distant, the *Sicilian* eighteen, and the *Calgarian* fifty-three. The fact that there was fog at Cape Race made no difference, and Capt. Thompson, the Commander, believes there are great possibilities for the system, especially in the event of going to the rescue of a ship sending out the S.O.S. call.

A new transmitting apparatus for wireless telephony, due to Herr L. Kühn, and developed by the Gesellschaft für drahtlose Telegraphie, was recently described in a German paper. The microphone current is passed through a winding over a soft iron core, on which is wound a second winding connected in the antennæ circuit. The self-induction of the latter coil varies according to the fluctuations in the microphone circuit, and the oscillations in the antennæ circuit therefore also vary in frequency accordingly. By this means, it is stated, an oscillation energy of 8 kw. in the antennæ circuit has been sufficiently influenced by a microphone energy of only 8.7 watts to effect a proper transmission of speech.

**High Voltages in Military Defence.**—The *Times* correspondent reports that barbed wire entanglements made live with a pressure of 1,500 volts formed part of the defences of Namur.

**The Shipping, Engineering, and Machinery Exhibition.**—It is formally announced that this exhibition, which was to have started on September 25th at Olympia, is to be postponed to some time between July and September, 1915.

**Theft at Foster Engineering Co.'s Works.**—An extraordinary case was heard last week at the Wimbledon Police Court, when George Kertland, of Shepherd's Bush, was charged with being concerned with two other men not in custody with stealing carbons and other goods value £2,000 from the works of the Foster Engineering Co. Most of the goods were found at an engineering works at Hayes, Middlesex. The prisoner alleged that he had the authority of the Treasury for his act, as the goods were "the property of an alien enemy." Any suggestion of the kind, however, is strongly repudiated by the Foster Engineering Co.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published August 20th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad

17,038/13. **Telephone Systems.** K. E. ERICSSON and J. DAHLSTRÖM. An improved relay system in which each of the stations which are to communicate with each other is connected to its own relay apparatus at a relay station. Each pair of lines entering the relay station is adapted to be connected either to the primary of a microphonic intensifying circuit or to the secondary winding of a transformer. When the subscriber at one station begins speaking, the magnified current produced in the microphone circuit operates a time relay switch through a transformer, thus disconnecting the outgoing line of the receiving station from its microphone circuit, so that no disturbing sounds are produced. When the speaking ceases, the switch comes back to the normal position after a short interval, and when the other subscriber commences to speak, the lines from the first station are in their turn disconnected from the microphone circuit. Five figures.

17,859/13. **Wireless Signalling.** R. C. GALLETTI. The specification describes an improved method of signalling by the use of unidirectional cyclic discharges (see ELECTRICAL ENGINEERING, May 29th, 1913, p. 310). Two sets of cyclic discharge circuits are used, one for sending the Morse signals and the other to take up energy during the intervals between the signals. This prevents arcing or sparking at the operating key, and enables heavy currents to be utilised. Two figures.

26,764/13. **Conduit Fittings.** J. R. A. HEMMING. The conduit is held in the socket by a transverse gripping screw in a lug at the side. In casting, the internal diameter of the socket is left small so that the transverse hole in the lug can be tapped without breaking through. The screw is then screwed into place, and the socket is bored out to the correct diameter, part of the screw being cut away in the process. The conduit can then be inserted, and is firmly gripped by giving the screw a quarter turn. Five figures.

8,711/13. **Starting Rotary Converters.** SIEMENS BROS. DYN. WKS., LTD. (*Siemens-Schuckert. Ges.*). When rotary converters are started up from the A.C. side, the polarity at the moment the machine comes to synchronism is a matter of chance, so that a reversing switch has to be provided in the field circuit. This invention ensures correct polarity by the use of an electrical valve in the exciting circuit, which valve only allows current to flow in one direction. It may consist of an iron-aluminium cell, and is connected in series with a regulating resistance and the field winding of the converter. A high resistance should be arranged in parallel with the cell to guard against an excess of pressure. One figure.

### Specifications Published To-Day

The following Patent Specifications will be published to day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** CONRADTY [Carbons] 22,223/13; WEINTRAUB [Vapour lamps] 6,352/14.

**Distributing Systems, Cables, Wires, and Insulating Material:** RUMOLINO [Control of marine engines] 26,733/13; COLD LIGHT (DUSSAND PROCESSES), LTD. [Lighting] 27,148/13; DOULTON and MORRIS [Troughs for cables] 27,409/13; ETILLE [Connection for relays] 7,201/14.

**Electrometallurgy and Electrochemistry:** CRAFTS [Furnaces] 18,072/13; HEUSER [Welding] 597/14.

**Ignition:** ROGALSKI [Interrupter] 26,338/13.

**Incandescent Lamps:** DICKER [Safety lamps] 5,088/13; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Lamps] 18,447/13; SCHAEFER [Lamp supports] 8,807/14.

**Instruments and Meters:** ONWOOD [Voltmeters and ammeters] 17,733/13; ROGOWSKI [Magnetic potential meter] 18,103/13; SZILARD [Electrometers] 20,008/13.

**Storage Batteries, &c.: BURGER [Galvanic cell] 15,463/13; THOMPSON [Unspillable accumulators] 20,216/13; HAMILTON [Pocket lamp batteries] 14,686/14.**

**Switchgear, Fuses, and Fittings:** AKT.-GES. BROWN, BOVERI ET CIE. [Liquid resistances] 18,000/13; SCHALCH [Contact device for lifts] 18,479/13; MERRILL [Regulators] 3,149/14; SIEMENS-SCHUCKERT. GES. [Circuit breakers] 10,082/14.

**Telephony and Telegraphy:** WESTERN ELECT. CO. (*Woodward*) [Telephone exchange system] 18,122/13; UNITED TELEGRAPH & CABLE CO. and BRUCE [Telegraphy] 18,321/13; MARCONI'S WIRE-

LESS TELEGRAPH CO. and ROUND [Wireless receivers] 18,326/13; MCGAURAN [Telephone call-recorders] 19,220/13; SIEMENS & HALSKE A.-K. [Telephone system] 19,271/13; CAMERON [Automatic telegraph systems] 20,773/13; LAVERY and BANDLOW [Telephone system] 4,619/14; CIE. FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON [Telephone instruments] 5,640/14; RYAN and EASTERN TELEGRAPH CO. [Duplex telegraphy] 10,794/14.

**Traction:** KODDERITZSCH [Retrieving device for trolley collectors] 19,475/13; BOIRAULT [Connection devices for vehicles] 21,480/13.

**Miscellaneous:** READ and BRANSOM [Electrically controlled valve] 17,926/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, Cables, Wires and Insulating Material:** STORER [Motor control systems] 17,465/14.

**Electrometallurgy and Electrochemistry:** SIEMENS & HALSKE A.-K. [Electrolysis of halogen alkalis] 17,089/14.

**Incandescent Lamps:** SEIFERT [Manufacture of tungsten wire] 9,874/14.

**Switchgear, Fuses and Fittings:** SIEMENS-SCHUCKERT. GES. [Starting switches] 17,949/14.

**Telephony and Telegraphy:** BOUCHARDON [Hertzian wave apparatus] 18,009/14; BLESSING [Telephone systems] 18,033/14; BETULANDER [Selectors] 18,076/14.

**Miscellaneous:** KIENZLE [Machine tools] 18,042/14; SIEMENS-SCHUCKERT. GES. [Signalling arrangements for searchlights] 18,125/14.

### Opposition to Grant of Patents

19,963/12. **Improved Magneto.** O. BÄRTSCH. The Comptroller has decided to allow the grant of this Patent.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** O. SCHAEFER [Lamp support] 9,510/08.

**Dynamos, Motors and Transformers:** E. A. CAROLAN (*G.E. Co., U.S.A.*) [Control of vapour rectifiers] 10,341/04; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Field windings for A.C. commutator motors] 10,457/04.

**Electrochemistry and Electrometallurgy:** A. CLEMM [Manufacture of phosphates] 9,443/05; A. HIORTH [Induction furnace] 28,959/06.

**Incandescent Lamps:** A. C. HYDE [Sealing-in wires for bulbs] 10,472/06.

**Traction:** P. BROWNE [Signalling system] 10,560/07.

**Miscellaneous:** ARMSTRONG WHITWORTH & Co. and E. W. LLOYD [Lamp signalling apparatus] 9,194/01.

### PROCEDURE TO OBTAIN SUSPENSION OF BRITISH PATENTS GRANTED TO GERMANS AND AUSTRIANS

ON August 7th a short Act of Parliament was passed authorising the Board of Trade to make regulations for avoiding or suspending any patent granted to the subject of a State at war with this country. The Act, and the regulation which has now been issued, are to be in force during the war and for a subsequent period of six months. It is open to anybody to apply for the suspension of any such patent, but the applicant must first satisfy the Board of Trade that the applicant "intends to manufacture, or cause to be manufactured, the patented article, or to carry on or cause to be carried on, the patented process," and also that it is to the interests of this country or to a particular trade that the application should be granted. All such applications will be the subject of special inquiries by a person or persons appointed by the Board, and it rests entirely with the discretion of the Board whether such applications will be granted or not, in every case.

The regulations also provide for an extension of time for proceedings under the Patents and Designs Act, 1907, and the Trade Marks Act, 1905, where the person concerned is on active service, or is prevented in any way owing to the war from continuing the proceedings meanwhile, or where the continuation of the proceedings would be prejudicial to the person concerned.

## "ELECTRICAL ENGINEERING" TRADE SECTION

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**HEATERS.**—A new leaflet to hand from Ferranti, Ltd. (Kingsway, W.C.), describes their 1914 type of electric fires. Spare elements are also kept in stock, so that renewals can easily be effected. Each fire is fitted with two elements and two switches, thus allowing two heats to be obtained.

**HEATING AND COOKING APPARATUS.**—A series of leaflets has been issued by Belling & Co. (Edmonton), and which can be obtained by application to the above address, gives the revised and reduced prices of their well-known types of electric heating and cooking apparatus, including boiling rings, grillers, the "Belling" griller-oven, and the "Office," "Portable," and "Standard" patterns of fires. The fact that all "Belling" fires are guaranteed for three years' severe service should suffice to indicate the excellence of their manufacture, and it is important to notice that these fires, like all "Belling" goods, are entirely British made. As the demand for domestic labour-saving appliances is sure to be augmented in the near future, we have no doubt that the Company's enterprising and patriotic policy will meet with the success it deserves.

**INSULATING VARNISHES.**—A leaflet from Chas. H. Blume (White Building, Sheffield) gives particulars of the several brands of the well-known "Megomac" and "Insulac" varnishes, which are manufactured in seven different grades to meet the requirements of a large variety of general work. The qualities of these varnishes can also be adjusted to suit any special service conditions which may arise.

### WATER-TIGHT FITTINGS AND SWITCHES

THE illustration reproduced herewith shows a chain-pull switch-box, designed for use in conjunction with "Simplex" watertight fittings. It consists of a watertight switch-box, the switch being operated by a rocker arm attached to a spindle which passes through a gland in the box cover. Simplex Conduits, Ltd. (Garrison Lane, Birmingham), in addition to the above switch, have also a similar pattern which is operated by turning a knob on the top of the box cover. On account of the objection which many engineers have to tube-end bushes made of wood or insulating material, the Company are introducing brass and lead bushes for this purpose.

CHAIN-PULL SWITCH.

### ROYAL EDISWAN LAMPS

WE give in the accompanying illustrations views of the glass works of the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex), which is one of the two lamp manufacturers in this country who have their own glass houses. All glass is made and blown in these works for the various bulbs used in the many sizes and types of Royal Ediswan lamps. Fig. 1 shows a part of the interior of one of the glass houses where experienced glass-blowers are seen at work. One of the operatives can be seen at the furnace gathering "metal," and two other operatives are seen blowing and finishing the bulbs off in the mould. This class of work is skilled, and requires a great deal of experience and careful handling. The glass houses are kept continuously running, the operatives working in three eight-hour shifts each. Considerable extensions to the existing Ediswan glass houses are being made to meet the increased business which is being negotiated on every hand for an All-British lamp. Fig. 2 gives an idea of the peculiar shape of the buildings, at the rear of which may be seen a series of storage rooms containing millions of Royal Ediswan bulbs ready for making into lamps.

The staff of the lamp manufacturing section is also being added to daily owing to the increased orders, and the engineer-

ing section of the works is likewise in a state of increased activity caused by Admiralty work. It may be noted here that the firm is paying the wives of married employees serving in the Army half pay, and will allow the men to take up their old positions upon return.

The Company are sending out a circular letter pointing out that owing to the advances in the prices of raw materials, withdrawal of their existing price lists is liable at any moment,

FIG. 1.—INTERIOR OF EDISWAN GLASS HOUSE.

although they do not propose to make any drastic alterations at present. Owing to their satisfactory position, however, with regard to stocks, they are able to fulfil all general requirements, and as regards stock of lamps their position is particularly favourable. The Company is showing great activity in the advertising line, and has just produced two very effective new showcards, one dealing with lamps and the other with All-

FIG. 2.—EXTERIOR OF EDISWAN GLASS WORKS.

British Ediswan fans. Another circular letter reminds the company's friends that Royal Ediswan lamps have been made with British capital as well as British labour ever since 1883.

The increase in the demand for radiator lamps has enabled the Company to reduce the list prices of these to 3s. 3d. for all voltages, and in connection with other types of radiators, it is interesting to note that they are supplying a quantity of Admiralty pattern Quartzalite radiators to H.M.S. *Tiger* being built by John Brown & Co., Clydebank.

**The Strength of Metal Filament Lamps.**—During the severe thunderstorm which passed over Dublin district recently, the overhead wires of the Dublin and Lucan Electric Railway were struck by lightning. The glass support of one of the Royal Ediswan "Downlite" lamps was fused, but on examination the filament was found to be intact. This is a good illustration of the wonderful strength of these filaments. The actual lamp is on show at the Dublin depot of the Edison & Swan United Electric Light Co., Ltd.

### MAZDA DRAWN WIRE LAMPS

WE called attention three years ago (see ELECTRICAL ENGINEERING, Vol. VII., p. 467, August 24th, 1911) to the announcement of the application of drawn-wire filaments to Mazda lamps, and the British Thomson-Houston Co. now remind us that from the very inception of the drawn-wire process all the wire used in Mazda lamps has been manufactured in Rugby. The wisdom of the Company in this course is more than ever evident in the present crisis, for they inform us that they are now absolutely independent of any other country for the supply of tungsten wire. This fact places them in a certain and safe position, and also assures the advantage to the trade and public of a continuity of supply. It will also be remembered that the introduction of half-watt lamps was first announced in Great Britain at Mazda House on August 26th last year, and we there saw samples of the first Rugby-made half-watt Mazda lamp. Ever since that time the British Thomson-Houston Co. have been busily engaged on the manufacture of these lamps, and it was with a feeling of satisfaction that we published the announcement last week that British-made half-watt lamps are now being produced in commercial quantities at Rugby. The British Thomson-Houston Co., Ltd., is thus in the satisfactory position of being able to guarantee that all its lamps—Mazda and carbon—of every type and size are made in Great Britain by British workpeople.

### ENCLOSED CIRCUIT BREAKERS

IN industrial work it is eminently desirable that circuit-breakers and other electrical gear shall, wherever possible, be totally enclosed. Amongst the apparatus which it is more difficult to enclose totally are circuit-breakers, but the General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, London, E.C.), have recently introduced a new design

"SALFORD" ENCLOSED  
CIRCUIT-BREAKER.

which is shown in the accompanying illustration. The circuit-breaker is fixed in a strong cast-iron case intended for mounting on a wall or angle iron framework. The lid is hinged and is interlocked with the switch. An important feature is the fact that the breaker can be opened and closed with the same handle—a great improvement over the use of a special lever for tripping.

### TENDERS INVITED AND PROSPECTIVE BUSINESS

#### Generating Stations, Sub-Stations, Mains, &c.

**Australia.**—The Victorian Railway Commissioners require low-tension switchgear and instruments, low-tension cable, and fuse-boxes and fuses. Further particulars at Board of Trade Intelligence Department, 73 Basinghall, St., E.C.

**Bradford.**—Electric lighting of Guardians Buildings at

Clayton (including generating plant). Clerk to the Guardians, August 28th.

**Chile.**—A generating station is to be erected at Cartagena by Don Francisco Soto. The plans have been approved by the authorities.

**Colwyn Bay.**—The proposed new power station is to be put in hand at once, in order to provide employment.

**Irlam.**—The Electric Lighting Sub-Committee recommends the employment of an expert to prepare an electric lighting scheme.

**Liverpool.**—An expenditure of £40,000 upon mains is to be incurred.

**London: St. Pancras.**—In order to assist in preventing unemployment it is recommended that extensions to the power station be put in hand. Additional mains are also to be laid.

**L.C.C.**—Induced-draught fans, motors, spare parts, and dampers at Greenwich power station. Clerk. September 22nd. (See an advertisement on another page.)

**Wimbledon.**—A Local Government Board inquiry was held last week concerning the loan of £8,500 for the purpose of laying two extra high-pressure cables throughout certain parts of the district, and also for the provision of a transformer sub-station. At present the mains serving the Merton and Maldens and Coombe district are 15 per cent. overloaded.

#### Wiring

**Huddersfield.**—Electric lighting, bells, telephones, &c., at Storther Hall Asylum. Engineer, West Riding Asylum, Wakefield. September 9th.

**Loughrea.**—The Loughrea Electric Lighting & Power Co. invites tenders for wiring consumers' premises. Secretary.

**Torpoint.**—Electric lighting fittings for Council offices. Borough Engineer. September 3rd.

**Warrington.**—Wiring of Evelyn Street Council School. Secretary, Education Committee.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Bury.**—Rebuilding mill for Bury Felt Mfg. Co.

**Eastbourne.**—236 houses. £60,000. Town Clerk.

**Edinburgh.**—Post Office Stores, Roseburn. H.M. Office of Works, London.

**Hull.**—Sanatorium. £14,500.

**Stratford.**—New packing warehouse. C. W. S., Ltd., Manchester.

#### Miscellaneous

**Australia.**—The Deputy Postmaster-General requires telephone instruments and switchboard parts. Further particulars at Board of Trade Intelligence Department, 73 Basinghall Street, E.C.

**Leeds.**—Four sections of tramway track. General Manager, September 7th.

### TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Basingstoke.**—The tender of Messrs. Leader & Co. has been accepted at £78 for wiring the generating station, and that of Messrs. Milsom & Co., at £77, for wiring the Town Hall.

**London: H.M. Office of Works.**—A contract for a twelve months' supply of Wotan drawn-wire tungsten lamps has been placed with Messrs. Siemens Bros. Dynamo Works, Ltd.

**L.C.C.**—A contract has been placed with Messrs. Siemens Bros. Dynamo Works, Ltd., for 125,000 Tantalum traction lamps. These lamps, we understand, have been used for the past two years on practically the whole of the L.C.C. tramways.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**British Made Woodwork.**—C. Jennings & Co., 955 Pennywell Road, Brixton, inform us that works are running as usual, and their various depôts are open to supply timber and woodwork of every description.

**J. H. Tucker & Co.**—This firm, who have for twenty years manufactured nothing but all-British goods, inform us that

# ALL OTHERS BOW BEFORE *The* **CRYSELCO** METAL FILAMENT LAMP.

## PHENIX ASSURANCE COMPANY, LIMITED. ESTABLISHED 1782.

Head Offices: 19 & 70, LOMBARD STREET, LONDON, E.C.

TOTAL FUNDS EXCEED	CLAIMS PAID EXCEED
<b>£16,000,000</b>	<b>£90,000,000</b>

CHAIRMAN: RT. HON. LORD GEORGE HAMILTON, P.C., G.C.S.I.

### FIRE - LIFE - ACCIDENT - MARINE

Loss of Profits following Fire, Workmen's Compensation, Fidelity Guarantee, Burglary, Trustee and Executor, &c.

#### ELECTRIC LIGHTING.

The Company has always encouraged the development of Electricity, and the well-known "Phoenix Fire Office" Rules for Electrical Installations are in use throughout the world. Copies will be supplied free on application to Head Offices.

General Manager: SIR GERALD H. RYAN.

**Ladders, Steps, Trestles, Scaffolds, &c.**

Sale or Hire.

**HEATHMAN & CO.**

10, Parson's Green, London, S.W.

HEATHMAN'S PLAIN DECORATOR'S TRESTLES. MADE IN TWO WIDTHS. NEW TOP TO TAKE ONE SCAFFOLD BOARD. NEW TOP TO TAKE TWO SCAFFOLD BOARDS. "FOR SALE OR HIRE"

**MARRYAT & PLACE**

DYNAMO & MOTOR HOSPITAL.

25, MATTON GATE, LONDON, E.C.

with the exception of certain raw material, they are practically independent of outside sources of supply, and are carrying on as usual, in addition to their well-known tumbler switches and accessories, the manufacture of a complete range of switch- and fuse-boards, &c.

**Ebonite.**—Mr. J. Martin Blair (53 New Broad Street, E.C.) has been appointed the London representative of an English firm of ebonite and vulcanite manufacturers, and will be pleased to have inquiries for rod, sheet, and tube, also battery boxes, telephone fittings, and turned and moulded goods. Mr. Blair also represents the Record Engineering Co., Ltd. (Manchester), for petrol, paraffin, and gas engines, and Broom & Wade, Ltd. (High Wycombe), for air compressors and hoists.

### LOCAL NOTES

**Chertsey: Electric Supply.**—The Rural District Council has informed the Ascot District Electricity Supply Co.—which has statutory powers in the district—that unless a supply is given at an early date, permission will be given to the Woking Electric Supply Co., who has offered a supply.

**Clones: Electric Lighting Postponed.**—Owing to the war, the Council has decided to defer further action regarding the electric lighting scheme for six months.

**South Shields: Hiring and Wiring Powers.**—There was a record profit of £3,484 upon the working of the Electricity Undertaking last year, after meeting expenditure amounting to over £1,000 upon such items as meters, equipment of office and showrooms, connecting new consumers, &c. Mr. H. S. Ellis, the Borough Electrical Engineer, is highly satisfied with the effect upon the undertaking of the new showrooms, all goods being sold, however, through contractors. The domestic heating and power units increased last year by 68 per cent. Attention is called to the handicap upon the undertaking by not possessing hiring and wiring powers, but in the absence of such powers it is recommended that a canvasser should be appointed in order to develop the business as much as possible. The Committee is also urged to facilitate the organisation of an up-to-date publicity department.

**Tasmania: State Purchase of Electric Power Co.**—A proposal for the purchase of the Hydro-Electric Power Co.'s undertaking is to be placed before the Government.

**Wallasey: The Diesel Engine Contract.**—A friendly arrangement has been come to between the Corporation and Messrs. Mirrlees, Bickerton & Day to put an end to the contract of April, 1912, for a Diesel engine driven alternator. The Company will take back the Diesel engine and the Corporation will retain the alternator at the price of £948. Since the contract was entered into, conditions have changed considerably, and the Corporation has embarked upon a large new steam-driven station.

### APPOINTMENTS AND PERSONAL NOTES

A borough electrical engineer is required at Swansea. Salary £500 per annum. Applications to Town Clerk by September 15th. (See an advertisement on another page.)

The South Indian Railway Co. requires the services of a fully qualified electrical engineer. Applications to Mr. Robert White, Consulting Engineer to the Company, 3 Victoria Street, S.W. (See advertisement on another page.)

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Newcastle & District Electric Lighting Co.**—An interim dividend at the rate of 3 per cent. per annum is announced.

**National Electric Construction Co.**—The proposal to reduce the capital to the extent of ten shillings per share, mentioned on p. 450 of our issue for August 13th, was sanctioned last week. At the ordinary meeting which preceded the special meeting it was stated that the war has interrupted negotiations for an important electric railway on the Continent. Estimates are being prepared in Baghdad for electric lighting and tramway undertakings there.

## ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

### EXHAUST STEAM PLANT AT A COVENTRY COLLIERY

AN example of modern method of electrical working in a colliery is to be found in the Coventry colliery of the Warwickshire Coal Co., where sinking operations are at present proceeding. One of the first steps in this scheme was the establishment of a large electric power-house with sufficient plant to afford an adequate supply of electric power for sinking, and with ample space for future extensions. In this colliery steam winding engines have been installed, and their exhaust is utilised in mixed pressure turbo-generators. There are two shafts 21 ft. 6 in. diameter and 180 ft. apart, with an approximate depth of 730 yds. A large brick building runs parallel to the line joining the centres of the shafts. The winding engines are installed one at each end, and the centre portion is allotted to the power-house. The boiler-house is a short distance away and contains a bank of six hand-fired Lancashire boilers. The exhaust steam from the winding engines passes through a Rateau-Morrison steam accumulator, which is of sufficient capacity to bridge over a stoppage of half a minute. In addition, there is a connection direct from the boilers to the mixed-pressure turbines, by

FIG. 1.—POWER HOUSE WITH COOLING POND IN FOREGROUND.

which the turbines can draw live steam when required. The condensing water is cooled in a cooling pond by the spray method. It is anticipated that with coal winding in full swing the engines will afford an average supply of 50,000 lb. of steam per hour at a pressure of 2 lb. per sq. in. absolute to the turbines, sufficient to generate 1,250 kw. continuously. The present generating plant consists of two 880 k.v.a. "Witton" turbo-alternators driven by the mixed-pressure turbines at a speed of 3,000 r.p.m. Three-phase power is generated at a pressure of 2,750 volts 50 cycles. The exciters for the turbines are direct-coupled, as shown in the view of the engine-room. A third and similar set will probably be installed. The air-pumps and other auxiliaries are steam-driven, with the exception of two centrifugal pumps giving a supply of 240 gallons of water per minute against a total head of 39 ft. These pumps are driven by 7.5 h.p. "Witton" motors. They are used for supplying water to cool the oil which lubricates the bearings of the turbines and for emptying the cooling pond. For lighting purposes there has been installed a 55-kw. "Witton" generator driven by a high-speed steam engine at 575 r.p.m. This gives a three-wire continuous-current supply at 230 volts across the outers, a static balancer giving the necessary neutral connection. The set is only used when the winding engines are not at work. When exhaust steam is available lighting current is taken from the main alternating-current supply, and the conversion from alternating to continuous current is effected by a 55-kw. "Witton" motor-generator running at 580 r.p.m. The rotor starter for this set is situated close to the machine. As with

the steam-driven lighting generator, the third wire connection is attained by a "Witton" static balancer, and acts as a stand-by exciter for the turbo-generator. The generators have been designed with high internal reactance in order to enable them to withstand heavy short-circuits without damage to the windings. Close regulation is obtained by means of a Brown, Boveri voltage regulator. The colliery works with an insulated neutral. The electrical plant was supplied by the

FIG. 2.—MIXED PRESSURE TURBO-GENERATORS.

General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, London, E.C.), and Mr. W. C. Mountain, of Newcastle-on-Tyne, is the consulting engineer for the scheme. We are indebted to Mr. A. M. Russell and Mr. J. W. Liddell, the agent and manager of the colliery, for permission to publish this description, and to Mr. W. C. Mountain for technical details of the plant.

### THE WHARNECLIFFE PIT DISASTER

THE inquest with regard to the explosion which took place at the Wharneckcliffe Silkstone Colliery on May 30th was concluded on August 15th. Since our last note on the subject (*ELECTRICAL ENGINEERING*, August 6th, p. 442) several more witnesses gave evidence with regard to the possibility of the explosion having originated in the coal-cutter, which was at work at the time. Mr. J. Wroe said that it was difficult to determine whether the defects in the machine caused the ignition, although everything pointed to the ignition having taken place at the machine. Mr. H. A. Abbott (Inspector of Mines) was also of opinion that the gas was ignited by a spark from the coal-cutter.

Evidence was also given by Mr. R. Nelson (H.M. Electrical Inspector of Mines), who was of opinion that the coal-cutter was very likely to have been the cause. In the condition in which he saw it, sooner or later it would "quite certainly" ignite inflammable gas if surrounded by it. He referred to a case where sparking from a motor on the same voltage was known to have produced ignition. That the motor had been sparking could be inferred from the condition of the commutator and the fact that the cover had been recently removed. The absence of signs of blast in the interior of the case was no proof that the explosion had not originated there. This point had been shown by experiments with a switch-box containing a piece of cotton-wool. The safety of electric coal-cutters was a question of maintenance. If a machine was perfectly maintained, it was safe.

The following verdict was finally given by the jury:—That the twelve men lost their lives by an explosion of coal-gas on May 30th, caused by the stoppage and re-starting of the fan with a defective coal-cutting machine running at the face causing ignition, and the jury are of opinion that the whole of the management have been very negligent, but not criminally so."

## MINING AND METALLURGICAL PATENTS OF AUGUST

### Mining.

TWO of the specifications published last month relate to the detection of dangerous gases in mines. No. 14,498/13, by G. Schauli, of Cheshunt, describes a system in which pipes are led from the pit-head to each separate working, so that samples of the gases can be drawn off and automatically tested for the presence of fire-damp and choke-damp. In specification No. 16,257/13, J. C. Rigaux, of Belgium, describes a combined lamp and fire-damp detector. The fire-damp detecting apparatus consists of a concertina device covered with platinum-black sponge which heats up and expands, thus opening a contact in the lamp circuit in the presence of fire-damp, causing the lamp to glow dimly. Specification No. 29,096/13, by W. Littlewood, of Barnsley, and No. 8,975/14, by J. A. Adlington, of Rotherham, both relate to signalling apparatus of the dial type. In the former the dial rotates to give the signal, and automatically returns to zero when the message has been complied with, whilst in the latter the signal is automatically recorded on a paper chart and remains visible until the next signal is given.

### Metallurgical.

In his specification No. 18,072/13, W. N. Crafts, of Oberlin, U.S.A., describes an improved construction of induction furnace of the type provided with a hearth basin for holding the whole of the charge. The core consists of two limbs of laminated iron passing through the lower portion of the hearth and united by external cross bars. The primary winding on these limbs is, of course, surrounded by a refractory casing, and the metal in the hearth forms the secondary. The hearth is arranged so that molten metal may be drawn off without disturbing the operation of the furnace. An improved form of electro-depositing tank of light and cheap construction forms the subject of specification No. 9,232/14. The patentee, W. Thum, of Hammond Lake, U.S.A., arranges suitable supports outside the tanks to bear the weight of the heavy electrodes. This allows a light construction of tank to be employed for containing the electrolyte.

**The Limiting Conditions for the Safe Use of Electricity in Coal Mining.**—A paper with this title, by Professor W. M. Thornton, read before Section G of the British Association in Australia, contained a summary of recent researches on the limits of electrical ignition of inflammable mine-gases and coal-dust. The lower limit of inflammability is 5·6 per cent. of methane in air by volume; a temperature of 200° C. lowers this to 5·1 per cent. The most inflammable mixtures are at 8 per cent. for continuous-current break-sparks, 10·2 per cent. for alternating-current breaks. Excess of nitrogen appears to markedly increase the necessary igniting current. With non-inductive circuits 1 ampere at 100 continuous volts is a typical value; the corresponding values with alternating current are 7 amperes at 40 cycles per second, 16 at 60, 20 at 80, and 29 at 100. By varying the inductance, the energy of an igniting break-spark is found to be constant at about 0·1 joule. Electric signalling bells have inductance up to 0·5 henry, and ignite gases at the trembler spark or signalling point. All electric lamps and fuses, however small, must be enclosed. Oscillations on a cable sheath caused by short circuits on the conductor will not ignite gas, but maintained leakage arcs from armouring are only slightly more active than break-sparks. Static discharges from 6-in. high-speed belting could not be made to ignite gas, nor the blue brush discharge from high-pressure conductors. Movements of clouds of dust have been shown to give electrification and to cause sparks, but the energy must be much greater than can be obtained experimentally in order that this should become dangerous. Wireless telegraphy operations on the surface do not induce sparking potentials underground. Capacity sparks in general from cables left insulated after being charged are very active, 0·002 to 0·005 joule causing ignition. The influence of gas in forwarding coal-dust explosions begins to be felt when  $\frac{1}{2}$  per cent. of gas is present. At 2 per cent. full ignitions are obtained at every trial. Coal-dust alone can be ignited by both continuous-current or alternating-current break-flashes, the former requiring 3·5 to 6 amperes at 480 volts in non-inductive circuits, the latter 14 amperes at 40 periods and on a power factor of 0·8. Continuous-current faults on the negative cable develop rapidly in the presence of moisture, and the cable is disintegrated. Alternating-current faults are self-healing, and a mechanical fault does not increase electrically on an alternating-current cable. Armouring is necessary under modern power conditions; lighting and signalling circuits must be equally well protected to prevent open sparking. The limits of safety are electrically low, but the risks of ignition are even now no greater than those attending the use of flame safety lamps, and they can be entirely prevented.

## AN ELECTRICALLY-DRIVEN FURNACE-CHARGING MACHINE

AN interesting part of the equipment of a steel works is the furnace-charging machine, used to lift the charging boxes which have been previously filled with pig-iron or scrap, and to empty them into the furnace. To effect this a large number of motions have to be provided for. An excellent method of loading the charging boxes is by means of "Witton-Kramer" lifting magnets, as shown in Fig. 1. The actual charging machine is shown in Fig. 2. A large horizontal steel bar may be seen on the left-hand side. This is carried by the machine, and slides horizontally into sockets in the charging

FIG. 1.—FILLING CHARGING BOXES.

box. By slewing round the arm together with the box, the charging machine traverses the length of the building until it arrives opposite the particular furnace to be charged. The arm is then adjusted in height, and the box thrust into the furnace, upon which the bar is revolved through 180° and the contents emptied into the furnace. On the completion of this operation the bar is withdrawn, together with the emptying box, slewed round, and the process repeated. There are in all seven motions, and although the duty imposed upon the machine is heavy—the loaded charging box weighing as much as 3 tons—the motions are fairly slow, and motors of no great size are needed. The following are the sizes of the motors and the speeds of the operation:—Hoisting, 20 h.p.

FIG. 2.—FURNACE CHARGING MACHINE.

at 40 ft. per min.; cross traverse, 40 h.p. at 220 ft. per min.; long travel, 60 h.p. at 300 ft. per min.; slewing, 10 h.p. at 6 r.p.m.; bar turning, 10 h.p. at 6 r.p.m.; auxiliary hoist, 10 h.p. at 20 ft. per min.; auxiliary traverse, 10 h.p. at 150 ft. per min. The charging machine which is illustrated was constructed by Wellmann, Seaver & Head (47 Queen Victoria Street, E.C.), the motors were supplied by the General Electric Co., Ltd. (Witton, Birmingham, and

67 Queen Victoria Street, E.C.), whilst the "Witton-Kramer" lifting magnet was manufactured by the Witton-Kramer Electric Tool and Hoist Co., for whom the General Electric Co., Ltd., are sole selling agents.

## CORRESPONDENCE CARBONS.

TO THE EDITOR OF *Electrical Engineering*.

SIR,—Our attention having been drawn to the article in your issue of the 27th inst., under the heading of "The Effect of the War on Street Lighting," we trust you will permit us to make the following observations:—The style of our firm is "Compagnie des Charbons Fabius Henrion," of which we are the London Branch, and are known as "Henrion Carbons." You mention that our factory at Nancy is small, but we would like to point out that our works at Pagny-sur-Moselle (not Nancy) is amongst the largest in the world, manufacturing carbons for open, enclosed, and flame arc lamps, and carbon brushes for dynamos and motors. Further, our output would compare quite favourably with Germany, and is about three times as large as Austria. Our factory is equipped on quite modern lines, and we are continually increasing our plant to meet the great demand for goods of our manufacture.

We would further like to add that since the outbreak of hostilities, we have supplied many thousands of carbons from stock to the most important corporations and industrial concerns, without charging the panic prices for which some vendors of carbons are asking, and about which many users are justly complaining. We have still a very fair stock, and also large consignments at Antwerp which we trust to get through shortly.

We trust you will give publicity to this letter, as we are anxious to correct the misleading impression that your article will probably make.

Yours faithfully,

HENRION CARBONS.

R. SERENA, Manager.

34 Victoria Street, Westminster, S.W.

August 31st, 1914.

## STANDARD CEILING ROSES

A STANDARD Specification (No. 67) for two- and three-plate ceiling-roses has been issued by the Engineering Standards Committee. The standardisation of plugs and other accessories is also being proceeded with, but it was thought advisable to publish the present specification separately to make it available as soon as possible. The main object has been to make it easy to replace a damaged fitting or cover without unduly hampering the design of these accessories. The Committee had the co-operation of the British Electrical & Allied Manufacturers' Association in preparation of the specification. The dimensions, screw-threads, position of holes, separating partition, &c., in the base and cover are defined, and a noticeable point is the use of different shaped plates for the different terminals for ease of identification in wiring. Some dimensions are given in inches and fractions, and some in mills.

**The Clifton Explosion.**—Evidence was heard as to the probable cause of an explosion at the William Pit, Great Clifton, on August 4th, in the course of the adjourned inquest on the victims on August 18th. According to some witnesses, the explosion originated in the neighbourhood of an electric pump just as the pump had been started, but the experts were divided in opinion as to the possibility of its having been caused electrically. Mr. W. C. Mountain was strongly of opinion that the explosion could not have started within the pump house, as it would have been difficult for a strong enough explosive mixture to be present, and there was no sign of explosion about the meter or switchgear. Mr. R. Nelson (H.M. Electrical Inspector of Mines), however, thought that appearances were consistent with the ignition having been caused by sparking at the starter, from which oil had leaked out. Mr. G. Poole (Inspector of Mines) agreed with Mr. Nelson, and thought it quite possible that an explosive mixture can have existed at the top of the pump house. There was often comparatively little force near the point of origin of the explosion. The jury found that it was impossible to say how the explosion arose.

**The Iron and Steel Institute.**—The autumn meeting which was to have been held in France is postponed, and no alternative arrangement has been made. The Papers that were to have been read will be printed, and members desiring to send in written contributions to the discussions are invited to apply for copies. The only Paper dealing with electrical matters is by Mr. L. Guillet on "Electrolytic Iron, its manufacture, properties, and uses."

## OPENINGS FOR THE EXTENSION OF OUR ELECTRICAL EXPORT TRADE

(Continued from last issue.)

**Australia.**—German electrical trade has increased greatly here during the past few years, and at a greater rate than British, although the United Kingdom still takes the lead. The comparative figures for imports in 1912 are:—

	From the U.K.	From Germany.	From Austria.
Dynamos and motors up to 200 h.p. ... ..	£185,000	£50,000	£1,000
Dynamos and motors over 200 h.p. ... ..	£30,000	£2,000	—
Regulating, starting and controlling apparatus ...	£26,000	£8,000	—
Fittings (metal or part metal) ... ..	£45,000	£10,000	—
Accumulators, batteries, arc lamps, insulated wires and cables, measuring instruments, insulating tape, &c. ... ..	£586,000	£59,000	£1,000
Arc lamp carbons ... ..	£1,000	£16,000	—

The British share of telephone switchboards and appliances has dropped from 44 to 35½ per cent. in three years, in relation to an increase in the trade from £105,000 to £164,000. Sweden and the United States are the chief competitors here. In porcelain insulators, not included in the above, Japan can quote the lowest price (but preference is given by the Post Office to goods not made by coloured labour), and Germany next lowest, Great Britain being quite out of the market in price. In electric lamps there is competition both with the German and with Dutch (Philips) lamps. Information as to the prospects of trade may be obtained from H.M. Trade Commissioner, Commerce House, Melbourne, and inquiries should take the form of a categorical series of questions.

**New Zealand.**—Up to 1912, Germany has only supplied direct about one-tenth of the electrical machinery attributed to Great Britain, but it is thought that the proportion is really greater, as the figures published refer to countries of shipment and not countries of actual origin. At all events, there is now much electrical work doing in New Zealand; Germany has been making a great effort to improve its position there, but there is every chance now of England regaining the proportion that Germany has acquired. H.M. Trade Commissioner reported on August 19th, in reply to a telegram, that an increasing demand for British goods may be expected, but prompt overtures should be made so as to anticipate competition from America.

**Canada.**—German competition has not been very keen, and the United States is our great competitor. H.M. Trade Commissioner reported on August 16th, in reply to a telegram, that the present financial condition of importers is generally satisfactory, and that British firms might extend their trade in carbons, electric apparatus, rubber, and zinc bars as the result of existing competition.

**India.**—It is stated that in 1912 about £270,000 worth of German electrical machinery was imported, but as Great Britain certainly far outdistances Germany in this market in India, it is possible that lamps are included in this classification. About 300,000 German metal filament lamps were bought in Germany in 1913.

**Egypt.**—German competition is of comparatively recent date, and the United States has been losing ground. On the other hand, Swiss competition has been keen for motors, &c.

**China.**—The German electrical imports are only slightly greater than ours. The introduction of electrical machinery for mines is worth attention, as mine-owners who have hitherto used primitive Chinese appliances are beginning to realise the advantages of up-to-date machinery. Last year it was reported that new electricity works were planned for Canton, Huchou (Chekiang), Tungchou (Kiangsu), &c. A Chinese tramway undertaking was started at Pekin at the end of last year with a capital of £750,000 for a 27-mile line. In Northern China it is recommended that direct connection with native firms should be avoided, and business confined to "foreign" importing firms already established on the market. The importation of German lamps is large throughout China. In Hong Kong the Germans have been supplying the bulk of the electrical materials used, but some Americans and British made lamps are also imported (B.C. caps are employed). America holds the market for fans.

**Japan.**—The German imports exceed British in all electrical apparatus except telegraph and telephone instruments, but only £1,000 of these latter were supplied from each country to Japan last year. The following are comparative figures for other electrical imports:—Insulated wires: Germany, £142,000; United Kingdom, £49,000. Meters: Germany, £15,000; United Kingdom, £3,000. Water turbines and Pelton wheels: Germany, £61,000; United Kingdom, £3,700. Dynamos, motors, &c.: Germany, £146,000; United Kingdom, £104,000. Incandescent lamps: Germany, £24,000; United Kingdom, £600. Ammeters and voltmeters: Germany, £5,500; United Kingdom, £2,900.

Japan does not manufacture turbines, but there are four or five companies manufacturing electrical machinery there, three of which are affiliated to American concerns. Japanese dynamos and motors are also exported to China. In addition, Japan has electric-lamp factories, although the imported lamps are considered superior. The following list gives some large hydro-electric plants for which inquiries have been issued, but orders not yet placed for machinery:—

Anglo-Japanese Hydro-Electric Co. (Hammamatsu district), one 2,900 b.h.p. set.

Seiyo Hydro-Electric Co. (Ise district), two 1,000 b.h.p. sets.

Hayadegawa Hydro-Electric Co. (Echigo district), three 2,350 b.h.p. sets.

Kyushiu Electric Light and Railway Co., three 3,850 b.h.p. sets.

The following is a list of large hydro-electric undertakings under construction in 1913-14:—

Inawashiro Hydro-Electric Co., six 11,250 b.h.p. sets. German turbines, English generators, German pipe line.

Kyushiu Hydro-Electric Co., five 5,600 b.h.p. sets. German turbines, U.S.A. generators, Japanese pipe line.

Kumamoto Hydro-Electric Co., four 2,150 b.h.p. sets. Swiss turbines, German generators, German pipe line.

Tone Hatsuden Kabushiki Kaisha, three 9,300 b.h.p. sets. German turbines, American generators, German pipe line.

Sagami Hydro-Electric Co., three 3,750 b.h.p. sets and three 2,350 b.h.p. sets. Swedish turbines, Swedish generators, Japanese pipe line.

Ibigawa Hydro-Electric Co., four 1,800 b.h.p. sets. German turbines, American generators, German pipe line.

Nippon Chemical Co. (near Wakamatsu), two 1,340 b.h.p. sets. Swedish turbines, German generators, Japanese pipe line.

Oji Paper Mill, Hokkaido, one 7,500 b.h.p. set. German turbine, American generator, German pipe line.

Kyoto Municipality, three 1,100 b.h.p. sets. Swedish turbines, American generators.

Government of Daito, Formosa: three 1,100 b.h.p. sets. Swiss turbines, German generators. Government of Rokkiri, Formosa, four 1,000 b.h.p. sets. Swiss turbines, German generators.

Bungo Electric Light Transmission Co., two 1,450 b.h.p. sets. German turbines, Japanese generators.

**Corea.**—The Gensan Hydro-Electric Co. and the Taikyuu Electric Co. commenced business at the end of 1912, and the Mokpo Electric Light Co., the Kunsan Electric Co., and the Seishu Electric Co. were expected to commence early last year; Messrs. Okura's undertaking at Shin-anju about last August, and the Shingishu Electric Co. about the end of last year. These all seem, however, to be quite small installations of less than 100 kw. each. The most promising towns have already been or are in course of being supplied with electric light and power, but the promotion of electrical enterprise continues nevertheless to occupy the attention of the Japanese authorities.

**Manchuria.**—The market for electrical supplies in Harbin is virtually in the hands of the local agency of a German firm and of another Continental firm who allow nine months' credit. There is practically no British electrical apparatus of any kind in North Manchuria.

**Norway.**—A certain amount of electrical machinery and other apparatus is manufactured in Norway, but the majority is imported from Germany, with smaller quantities from the United States, Sweden, and England. Electric current is cheap. There is some considerable sale for electric irons.

**Sweden.**—Although electrical supplies are extensively manufactured in Sweden, imports from foreign countries are considerable, especially from Germany. Lamps, lamp-holders, insulators, and wiring material are all imported, although there are a few Swedish factories. Edison screw sockets are used, and iron Bergmann conduits to a large extent. There are no large dealers in electrical supplies, and the business is in the hands of contractors, who do installation work and carry more or less limited stocks. Attention is only given to catalogues, &c., quoting on the metric system.

**Portugal.**—Although no up-to-date statistics are available, it is understood that Germany is sending more electric plant to Portugal than does the United Kingdom.

**Spain.**—The figures for German electrical exports to Spain, published in ELECTRICAL ENGINEERING of August 13th, are in all cases far greater than those from the United Kingdom, especially in the case of dynamos, motors, lamps, meters, and telegraphic apparatus. In fact, in everything but cable (which is apparently bought in nearly equal quantities from England and Germany, and also partly from some Spanish factories) and telephonic apparatus (which comes almost exclusively from Sweden and France), Germany supplies the greater part of the electrical trade. Some meters and electric heating apparatus are made locally, and there are also ten lamp factories, which, however, do not supply anything like the whole demand. Over two million German metal filament lamps were sold in Spain last year. The use of electric power is greatly extending.

**Italy.**—Electric cooking apparatus and irons have been imported from Germany. The extent of other electrical imports from Germany will be seen in the lists published in our issue of August 13th.

**Poland.**—According to the British Vice-Consul at Warsaw,

"the trade in electrical machinery and plant is entirely in German hands."

**Roumania.**—The volume of electrical trade is not large, but a number of provincial towns possess their own generating stations. Most of the machinery, lamps, and accessories is supplied from Germany and Austria, who have their own representatives. English is not much spoken, and catalogues in English are useless to send.

**Greece.**—Numerous firms have been established during the past ten years for the sale of smaller installation material, and their requirements are chiefly supplied from Germany. The Electrical Co. and the Gas Co. buy most of their material from their parent houses in France. Large extensions of telegraphs and telephones are projected by the Government.

**Argentine Republic.**—The powerful German company "Compañía Alemana Transatlántica de Electricidad," which supplies Buenos Ayres with electric light, makes all its purchases through Berlin. Germany has also a large connection in Rosario, and two leading American manufacturers are also represented in these places. There is no doubt that a large extension of British trade will be possible, but it is reported by telegraph that banks are for the moment refusing to give credit, and money is scarce in consequence.

**Chile.**—Practically all the electric light companies of the Valparaíso district are German and favour German supplies, and in the Valdivia and Llanquihue provinces are largely populated by Germans. The English language is little understood.

**Ecuador.**—Many municipalities intend to introduce electricity. Correspondence should be in Spanish.

The Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, E.C., will send copies of the pamphlet from which we have quoted most of the above notes to any *bona fide* manufacturer, and in some cases additional information may be available if specific questions are asked. The Department is, we understand, inundated with correspondence as a result of the publicity given to the "Trade War" idea in the general Press, so that requests for information in general terms should be avoided, and inquiries should state very definitely the particulars required.

The Commercial Intelligence Branch of the Board of Trade have also prepared lists of articles which inquirers desire (a) to purchase and (b) to sell. The first list states that inquiries have been received from firms desiring to purchase aluminium, general brassware, glass, glassware, china, and earthenware for electric fittings, celluloid cases, enamelled copper wire, magnets, magnetos, papier-mâché covers, and vulcanite rods, sheets, and mouldings for electrical apparatus, electric lamps and globes for same, and thin gutta-percha. Under section b, the list includes nearly every class of electrical goods. The lists may be obtained on application to the branch, and firms interested in any of the goods mentioned, either as buyers or sellers, should communicate with the director.

An enlarged sample room will also be established very shortly for the purpose of exhibiting samples of German and Austrian or Hungarian goods or materials which have competed with British products at home or abroad, especially those which are necessary for the continuance of British manufacture, but which it is now impossible for them to obtain from their previous sources. Firms who may wish to exhibit goods are invited to make application to the Commercial Intelligence Branch. It should be expressly understood, however, that the exhibition is intended exclusively for samples of goods which have formerly been obtained in Germany and Austria-Hungary alone and which firms may now desire to purchase in the United Kingdom. Notice will be given of the opening of the exhibition. A catalogue library will also be opened, and firms who may not desire to exhibit samples are invited to furnish catalogues of goods formerly received by them from Germany and Austria-Hungary, these catalogues to be classified by trades in order to be readily accessible to inquirers.

**The School of Mines, Treforest.**—A prospectus which we have received from the South Wales and Monmouthshire School of Mines at Treforest, which works in connection with the University College of South Wales, Cardiff, gives details of the very complete courses in mining engineering and allied subjects. The school is equipped with extensive laboratories, and a special feature is made of the Department of Electrotechnics, in which the principal lecturer is Mr. F. H. Downie. The next term commences on October 6th, and full particulars can be obtained from Mr. H. M. Ingledew, secretary, 4 Mount Square, Cardiff.

**The Northampton Engineering Magazine.**—The latest issue of the magazine of the Northampton Engineering College Union Society contains a number of contributions dealing with technical and non-technical matters of interest to students of the college, including abstracts of Papers read before the society.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,407.

What is the best procedure for the hardening, tempering, or other heat treatment of steel for the manufacture of permanent magnets of great constancy for measuring instruments?

(Replies must be received not later than first post Thursday, September 10th.)

### ANSWERS TO No. 1,405.

Two Chamberlain and Hookham ampere-hour meters, normally connected to read the "charge" and "discharge" current of a battery, were so connected that both meters read "discharge" current. This was done so that the "charge" meter (which accurately registered "charge" ampere-hours) could be used as a check on the "discharge" meter. But on comparing the two meter readings, the "charge" meter was found to be 18 per cent. slow, with the "discharge" meter. What is the explanation of this?—"DELTA."

The first award (10s.) is given to "F. R. C. R." for the following reply:—

As your correspondent mentions that the charge meter reads accurately, I take it that this has been recently checked, and is known to be correct. Very frequently it is arranged that one of a pair of battery meters reads incorrectly, so that if at the end of each charge the readings on both meters are the same, it is ensured that a certain percentage more current is put into the battery than is taken out. This tends to keep the battery in good condition. The usual method is to arrange for the charge meter to read 10 per cent. or 15 per cent. slow, and the discharge meter to read true ampere-hours. Occasionally, however, although this method is not so good, the charge meter is made to read truly and the discharge meter 10 per cent. or 15 per cent. fast. Possibly this has occurred in the case given, and the remaining 3 per cent. is easily accounted for, as each meter may be reading  $1\frac{1}{2}$  per cent. out in opposite directions. Another possible explanation is that the magnetic circuit of the discharge meter has at some time been broken, which would, of course, reduce the strength of the permanent magnet; in this type of meter the driving force is proportional to the magnetic force, whereas the braking effect is in proportion to the square of the magnetism. Consequently, if the strength of the magnet were reduced, the meter would speed up.

The second award (5s.) is made to "M.," who writes as follows:—

The reading of a B.O.T. meter or watt-hour meter is proportional to the product of the current and the volts in circuit, and as either of these may vary, it is necessary to provide the instrument with both a series and a shunt winding. In the case of a meter being used on a constant voltage circuit, the effect of the shunt winding will be a constant quantity. It is, therefore, possible to dispense with

the shunt winding in these circumstances, and so to reduce the cost of the instrument, but the calibration can only be made on the assumption that the voltage will remain absolutely constant. Such an instrument is called an ampere-hour meter, and it will only read correctly on the voltage for which it has been calibrated. When ampere-hour meters are used for measuring the charge and discharge current of a battery, they must be calibrated to suit different voltages, because the average discharge voltage of a battery is 2 volts per cell, whereas the voltage required to charge varies, according to the state of the cells, between approximately 2 volts and about 2.7 volts, so that the average charging voltage of a battery may be taken as approximately 2.35 volts per cell. If, therefore, we couple the charge and the dis-

charge meters in series, then the respective readings obtained will be as follows:—

Let  $R_1$  = Units read on charge meter.  
 $R_2$  = " " " discharge meter.  
 $i$  = Current.  
 $n$  = Number of cells.  
 $t$  = Time in hours.

Then  $R_1 = 2.35 \text{ int.}$ , and  $R_2 = 2 \text{ int.}$

Hence the reading obtained on the charge instrument will be 17.5 per cent. higher than that on the discharge meter, which is apparently what the questioner found to be the case. The questioner states that the "charge" meter was found to read 18 per cent. slow. This obviously was intended to mean high.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published August 27th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

**Names in italics indicate communicators of inventions from abroad.**

18,000/13. **Liquid Resistances.** AKT.-GES. BROWN, BOVERI ET CIE. The electrodes are suspended in a vessel, the lower end of which is sealed by liquid contained in a tank beneath. This tank is suspended on ropes which pass over pulleys, and is counterbalanced by suitable weights, so that it may be raised or lowered easily. Raising this tank decreases the resistance. No flexible leads or rubbing rings and brushes are needed. The specification also describes a method of maintaining the required quantity of liquid in the tank by means of a float valve. Two figures.

18,321/13. **Telegraphy.** UNITED TELEGRAPH & CABLE CO. and H. BRUCE. A system by which alternating or interrupted current can be used for ordinary telegraphic signalling, particularly over ocean cables. An alternator is used as the source of supply, one pole being earthed and the other connected to the line through a transmitting key, a condenser, and a sensitive relay. The signalling apparatus, which is the same at each station, consists of a sensitive relay controlling a sluggish relay, which in turn operates the contacts in the battery circuit of the sounder. The sensitive relay responds to the alternations of the current and keeps the sluggish relay energised until the circuit is broken at the transmitter key. Hence the sounder is not affected by the alternations. When alternating current is used for transmission, the capacity and resistance of the cable do not interfere with the speed of working, as in the case of direct-current systems. One figure.

18,447/13. **Improved Incandescent Lamps.** B.T.-H. Co. (G.E. Co., U.S.A.). A device for increasing the useful life and maintaining the initial efficiency of tungsten filament lamps. A small quantity of potassium thallium chloride is contained in a small open tube inside the bulb. Before the latter is sealed, a small quantity of pure dry nitrogen is admitted at a pressure of from 10 to 50 microns. One figure.

22,223/13. **Manufacture of Arc Lamp Carbons.** C. CONRADTY. Relates to the manufacture of carbons which are coated on the outside with a mixture of chemicals. Before the coating is applied the hard outer skin of the carbons is removed, e.g., by sand-blasting, leaving a rough porous surface to which the chemicals adhere very firmly.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** RAILING and ANGOLD [Automatic shunting devices] 24,074/13.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** CUNLIFFE & CUNLIFFE [Cables for power transmission] 18,170/13.

**Dynamos, Motors, and Transformers:** WADE (Heyman) [Converter] 25,846/13.

**Electrometallurgy and Electrochemistry:** MACKENZIE (Automatic Welding Co.) [Tube-welding machines] 15,858/13; BEAVER and CLAREMONT [Joining apparatus] 21,646/13.

**Heating and Cooking:** BERRY [Supply of electricity for heating] 16,040/13.

**Ignition:** CAMPBELL [Spark plugs] 2,628/14.

**Storage Batteries:** DININ [Accumulators] 14,119/14.

**Switchgear, Fuses and Fittings:** HOLT and SMITH [Circuit

breakers] 24,594/13; B.T.-H. Co. and WEDMORE [Switches and fuses] 27,182/13; YOUNG [Fuse-holders] 28,075/13.

**Telephony and Telegraphy:** MARCONI and ENTWISTLE [Transformers for high-frequency currents] 18,502/13; FESSENDEN [Submarine signalling apparatus] 18,765/13; THOMPSON (Soc. Anon. des Telegraphes Edouard Belin) [Transmission of photographs] 19,966/13; GELL [Telegraphic receiver] 21,036/13; C. F. CASELLA & Co. and ABRAHAM [Perforator] 26,252/13; WESTERN ELECT. Co. (Woodward) [Relays] 3,699/14.

**Traction:** FRANCHIMONT and CÉSAR [Operation and locking of rail points] 13,682/13; STABIE [Train-control systems] 18,008/13; WILLOCO, REGNAULT ET CIE [Starting and lighting of vehicles] 3,919/14.

**Miscellaneous:** BANFIELD [Intermittent driving] 66/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Incandescent Lamps:** FORNANDER [Portable lamp supports] 10,395/14; A.E.G. [Incandescent lamps] 18,369/14.

**Telephony and Telegraphy:** PIERCE [Relay apparatus] 15,681/14; SIEMENS & HALSKE AKT.-GES. [Telephone installations] 18,239/14.

The following Amended Specifications may now be obtained:—

**Incandescent Lamps:** C. TRENZEN [Manufacture of ductile tungsten] 26,800/12; F. H. REEVES [Anti-vibrator for lamps] 19,857/13.

### Amendment

14,741/13. **Regulator for Accumulator Charging.** W. H. SCOTT. In pursuance of leave previously granted, the above Specification has been corrected.

### Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

15,748/00. **Arc Extinguisher for Fuses and Switches.** G. W. PARTRIDGE. A small metallic vessel containing compressed carbon-dioxide and having a fusible end, is arranged in the switch or fuse-box so that if an arc forms, the end of the vessel melts and a jet of gas rushes out to extinguish the arc. Two vessels may be used if necessary, and they should be easily replaceable. The claims also include for the use of an explosive cartridge which is fired when the arc forms, so that the rush of gas extinguishes the flame.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** A. E. G. [Power transmission systems] 11,400/09, 13,798/09.

**Ignition:** H. H. LAKE (Fabrik Elektrischer Zünder Ges.) [Blasting fuses] 9,966/05.

**Instruments and Meters:** G. CHARLTON [Pressure gauge] 10,984/09; C. R. DARLING [Thermometer] 11,187/09.

**Switchgear, Fuses and Fittings:** B.T.-H. Co (A.E.G.) [Motor controller] 11,070/07; W. C. KIRWAN and K. QUANEY [Mercury switch] 26,088/09.

**Telephony and Telegraphy:** G. ERDMANN [Wireless signalling] 10,156/08.

**Miscellaneous:** P. T. SIEVERT [Glass manufacture utilising an electric arc] 10,842/03, 10,843/03; A. P. JONES ("Long Arm" System Co.) [Operation of bulkhead doors] 9,871/05.

# BELLING FIRES ARE FAR AHEAD OF ANY COMPETITORS

in  
Recognised Reliability,  
Sound Mechanical Construction  
and  
General All Round Efficiency.

## OUR GREATLY REDUCED PRICES

(which we shall be able to maintain for some considerable time owing to our big stocks) are now far below those of other makes (imitations or not); so that it is with confidence we shall this week send you a copy of our complete catalogue, showing amongst many others fires with 4 bars, 2 switches, 2 heats taking 2 units, 30/- list.

**BELLING & CO.,**  
DERBY ROAD,  
EDMONTON - LONDON, N.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

We trust that the Government is not overlooking the immediate necessity of laying further cables in the English Channel to supplement the few cables which are at present in existence to the west of the numerous ones which land near Calais and Boulogne, as it is, of course, possible that attempts to cut the latter may be made by our practical and well-informed enemy. Cables further west would be safe from attack, and their land-line connections in France easier to guard. Cable-laying at this season of the year is a comparatively quick and easy operation, and it occurs to us that there may actually be a sufficiently long cable "in stock" which was originally destined for another purpose. A cable across the Channel could be laid, jointed, and connected up in two days on emergency; there are men and cable-ships in the country who could do this at once, and even if a cable had to be made it is not impossible that this could be done in sufficient time for it to be of utility.

In answer to a question in the House of Commons on Monday, the Postmaster-General said it was not thought advisable at present to relax the regulations prohibiting the use of codes for cabling to distant countries.

Telegrams in English and French can now be accepted for Switzerland.—On August 27th the Netherland Indies Administration stated that telegrams sent by belligerent Governments or their representatives could only be written in clear Dutch, French, English, or German, and must bear the signature of the sender. Any telegrams containing particulars of movements of troops or naval vessels are not admitted under any circumstances.—The Press stated on the same date that the wireless installation in Togoland had been destroyed by the Germans before the Colony surrendered to the English Forces; and also that the French Government prohibited the use of wireless on merchant ships in French ports and territorial waters, as confirmed by the Board of Trade.—The Austrian Government does not accept or permit in transit telegrams for Japan. A similar notice was also issued by Hungary.—The Japanese Government notify that there is no longer any language restriction on telegrams for Japan.—The New Zealand Government has taken control of the wireless station in Apia in the Samoan group.—Owing to an interruption of land-lines in Mexico, communication with British Honduras has been cut off, and messages can only be sent by post from New Orleans.

The Directors of Marconi's Wireless Telegraph Co. announce their regret that, owing to the present impossibility of obtaining repayment of money lent by the Company on short loan against securities prior to the moratorium, they are compelled to postpone posting the dividend warrant, which otherwise would have been issued on Monday.

A course of twelve advanced lectures on the theory and practice of Radiotelegraphy, by Prof. J. A. Fleming, will commence at University College on October 28th. Six will be given before, and six after, Easter. The fee for each group of six is £1 11s. 6d. The syllabus includes theoretic considerations, production, and detection of oscillation, high-frequency measurement, practical wireless telegraphy and apparatus, problems of transmission, and recent developments.

**Uses of X-Rays.**—An article in a recent number of the *General Electric Review* describes some interesting applications of the Coolidge "X"-ray tube, the British Patent for which was published a short time ago (see *ELECTRICAL ENGINEERING*, July 30th, p. 432). In addition to the well-known uses of X-rays in the medical world, both for photographic purposes and for the treatment of certain complaints, other fields of application are found in botany and biology. Photographs can be obtained showing the various stages in the development of plants or animals. Thus it is possible to observe the gradual formation of a chicken inside the egg. It is interesting to note that whilst diamonds are practically transparent to the rays, counterfeit stones are almost opaque.

**MARRYAT**  
**ARMATURE**  
**REPAIRS**  
**DYNAMO & MOTOR HOSPITAL,**  
**28, HATTON GATE, LONDON, E.C.**

## "ELECTRICAL ENGINEERING" TRADE SECTION

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**FITTINGS AND ACCESSORIES.**—A fine illustrated catalogue is to hand from J. & W. B. Smith (15-23 Farringdon Road, E.C.). An enormous variety of electrical fittings and accessories are dealt with, including shades and reflectors, conduit fittings, radiators, cookers, fans, bells, and other articles too numerous to mention here. The lampshades can be supplied in either glass, bead, or silk, and in the latter connection a number of tasteful patterns of the various materials in stock, which are included in the catalogue, should be of assistance to prospective buyers who are unable to pay a personal visit to the showrooms. The large range of indirect lighting fittings to which a number of pages are devoted bear the marks of careful design, in which every care has been taken to ensure a pleasing effect without sacrificing mechanical strength. A point of interest at the present moment is that practically all the goods which are listed are British made.

**NOVELTIES.**—A leaflet from the Standard Trading Co. (25 Victoria Street, S.W.) calls attention to a pretty little miniature arc lamp forming a charm for the watch chain or a lady's bangle. We understand that these are made in this country.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**ROLLING STOCK.**—The latest pattern of steel car bodies with centre as well as end doors, used on the Bakerloo Tube Railway, is illustrated in the *Brush Budget*.

**ELECTRIC IRONS.**—A card from the British Prometheus Co. (Salop Street Works, Birmingham) illustrates three patterns of electric irons.

**BELL PUSHES, &c.**—A new list of bell-pushes, push-keys, and kindred accessories, has been issued by A. P. Lundberg & Sons (477 to 489 Liverpool Road, Islington). Most of these are fitted with the Company's patent "Pixy" push movement, with its parallel movement and real platinum contacts. This is mounted in a number of styles for flush and surface work, and also made up in pendant form. Substantial designs of push-switches with spring-on or spring-off action are listed, including special forms for use in narrow situations. Plugs and sockets for bell circuit connections are also dealt with.

### A LARGE SWITCHBOARD

**DURING** the recent Convention of the Incorporated Municipal Electrical Association in Birmingham, it will be remembered that a visit was paid to the Witton works of the General Electric Co., Ltd., of 67 Queen Victoria Street,

LARGE SWITCHBOARD FOR CARDIFF.

London, E.C. Among the equipment in course of erection which was inspected was a large continuous-current switchboard which has just been constructed for the Cardiff Corporation.

This board consists of twenty-five panels, and is over 45 ft. in length. It has been designed for controlling a supply for both lighting and traction purposes. The panels themselves are constructed of fine white marble, and, as will be seen from the illustration, the board presents a very attractive appearance. An innovation for heavy current switchboards has been embodied in the arrangements for the back of the board. Instead of being carried from the usual brackets, the busbars are supported by the stems from the switches. These stems, therefore, serve both for a mechanical support and for the current-carrying connection.

### NEW FITTINGS FOR INDIRECT LIGHTING

**THERE** are some cases where the use of indirect lighting has not been adopted owing to objections to the use of ceiling fittings. To meet this, the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), has brought out a series of designs of wall brackets for indirect

SHERATON DESIGN BRACKET FOR INDIRECT LIGHTING.

lighting, of which one is illustrated here. These are made with one, two, or three arms, and employ exactly the same kind of upturned reflectors as is familiar in the older suspended bowl fittings. A number of different designs to harmonise with various styles of decoration are made.

**Dispute as to Ownership of Carbons.**—We published a note last week (*ELECTRICAL ENGINEERING*, August 27th, page 473) on a case of alleged theft of a stock of about £2,000 worth of arc lamp carbons from the works of the Foster Engineering Co. at Wimbeldon. It now appears that the carbons were removed by representatives of the Beck Engineering Co., who claim that since the determination of an agreement between them and the Foster Co. the stock of carbons is their property. The matter is to be settled in the High Court, and Mr. Justice Shearman, we are informed, had already made an order for the carbons to be held by the Foster Co. pending the result of the action. Meanwhile the persons who removed the carbons by motor vans in the middle of the night from the Foster works have been committed for trial.

**Birmingham Manufactures.**—The Commercial Year Book of the Birmingham Chamber of Commerce, which contains very full information as to the industrial resources of the Birmingham district, including a considerable section on electrical matters, should be of special utility at the present time in connection with the efforts that are now being made to recapture the trade which has gone to our enemies.

**Ediswan Lamps.**—We are informed by the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex) that rapid advance is being made in their extra glass-blowing accommodation, with a view to supplying the demand for lamp bulbs hitherto met by Germany. We are pleased to hear that the employees have joined almost in a body the Rifle Club formed by the Company.

**The British Engineers Association.**—We have received a copy of the revised edition of the official Directory of this association, which includes classified lists of British manufacturers of all classes of engineering appliances. The primary object of the association was to assist British export trade to China, but in the present situation this Directory has a wider interest.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Australia.**—Three-phase motors for driving workshop and other machinery are required for the Melbourne Suburban Railways. Consulting Engineers, Merz & McLellan, 32 Victoria Street, London, S.W. Tenders to the Agent-General for Victoria, Melbourne Place, Strand, W.C., by October 12th.

**Barford (Warwick).**—A local electric lighting company is being formed. Mr. Smith Ryland is Chairman.

**Cleckheaton.**—Switchgear and feeders are required. Borough Electrical Engineer.

**Eccles.**—Coal elevator and conveyor. Borough Electrical Engineer. September 21st.

**Portrush.**—The electric lighting scheme prepared by Messrs. J. Woodside & Co., of Belfast, estimated to cost £8,000, is to be proceeded with. A loan is to be applied for.

**Spain.**—H.M. Consul at Barcelona reports that the hydro-electric schemes which are in course of realisation have discouraged the importation of steam engines and boilers, but have stimulated the imports of electrical machinery.

**Warrington.**—Twelve months' supply of earthenware conduit. Borough Electrical Engineer, September 15th.

### Wiring

**Aberdeen.**—Torry United Free Church (£5,000).

**Blackpool.**—Printing works for H. Maxwell & Co.

**Bromley (Kent).**—New infirmary.—Two schools (£26,000).

**Darwen.**—Public baths. Borough Engineer.

**Eccles.** School at Winton.

**High Wycombe.**—Workmen's dwellings (£11,200).

**Huddersfield.**—Public baths. Cambridge Road.

**Ipswich.**—Isolation hospital (£8,000).

**Watford.**—New infirmary. £10,500.

### Miscellaneous

**Australia.**—Telephone instruments, measuring instruments, and carbon- and metal-filament lamps. Deputy Postmaster-General, Sydney. October 7th. Further particulars at 73 Basinghall Street, E.C.

**Burnley.**—Electrical supplies for Guardians. Clerk.

**New Zealand.**—Wall telephones. Public Service Stores Tender Board, Wellington. September 8th. (This information is only of use to firms having agents in New Zealand who can be instructed by cable).

**Warrington.**—Electrical supplies for Guardians. Clerk. September 9th.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Bradford.**—It was stated in yesterday's *Times* that the order given some time ago by the Electricity Committee to a German firm for a 5,000 kw. turbo-generator was yesterday

transferred to the Westinghouse Co., Manchester, "who accepted it at a specially low price to find employment for their workpeople."

**Edinburgh.**—A contract for cable has been entered into with the British Insulated & Helsby Cable Co., Ltd., in substitution of one placed with a German firm a short time ago.

**London: H.M. Office of Works.**—A contract for twelve months' supply of standard type "Royal Ediswan" drawn-wire, and also "Royal Ediswan" carbon and special type lamps, has been placed with the Edison & Swan United Electric Light Co.

**Manchester.**—Messrs. Chamberlain & Hookham have received a contract from the Corporation for the supply of meters.

## LOCAL NOTES

**Bridlington: Electricity Profits.**—There was nett profit of £1,378 on the electricity undertaking last year. Of this, £356 has been spent on meters and £500 placed to renewals fund, the remainder being left as a floating balance in the treasurer's hands.

**Brighton: "Stealing" Electricity.**—The local magistrates last week convicted Rose Roper, of Grand Parade, for fraudulently consuming electricity. The defendant had a shilling slot meter, and it was found that the cable had been tampered with so that a large quantity of the current was not registered. A fine of forty shillings was imposed.

**Cleckheaton: Extensions Postponed.**—The Council has decided to defer proceeding with the projected extension scheme in its entirety for two reasons. One is that negotiations are to be opened up with the Yorkshire Electric Power Co. for a bulk supply, which many people in the town favour, and the other is the amalgamation with Liversedge and Gomersal, the inhabitants of which it is felt should have a voice in the matter.

**Clones: Electric Lighting.**—The power house of the Clones Electric Light & Power Company was put into operation last week. A feature of the installation is the complete system of street lighting, which consists of a combination of centrally-suspended clusters of lamps, and bracket lamps.

**Haslingden: Half-Watt Lamps.**—The Electricity Committee has expressed its satisfaction with experiments with half-watt lamps.

**Llanidloes: Purchase of Electric Supply Co.**—A Local Government Board inquiry was held last week concerning a loan for purchasing the local electric supply company.

**Sheffield: Street Box Explosion.**—Two explosions in street boxes on Sunday caused some little excitement. It is said that the metal cover of one box was blown as high as a house, but fortunately nobody was injured.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**British-Made Woodwork.**—C. Jennings & Co. (955 Pennywell Road, Bristol), announce that they are giving usual credit terms, and are endeavouring to keep the whole of the works going, especially in the direction of lines of woodwork previously made abroad.

**Bankruptcy.**—The trustee in the bankruptcy of F. T. Johnson, Electrical Engineer, 60 Eltesley Avenue, Cambridge, has been released.

**Telephone Apparatus.**—The Sterling Telephone & Electric Co., Ltd. (210-212 Tottenham Court Road), announce that the discount off all their lists except the following, is now 20 per cent. instead of 33½ per cent. The prices in the lists of military telephones, apparatus for wireless telegraphy, and blasting machines are withdrawn, and the advance of 10 per cent. in the prices of bells and indicators is now withdrawn.

**Change of Address.**—Simplex Conduits, Ltd., have removed their Liverpool branch from 1 Dawson Street to more extensive premises at 96 Whitechapel, Liverpool, where greatly increased stocks are now held.

**Electric Clocks.**—Gent & Co., Ltd. (Leicester), remind us that their "Pulsynetic" clocks are made entirely in England, and that they were the introducers of "Sinevar" British-made non-expanding nickel-steel, with which all their pendulums are made.

Telephone No.: 5509 Holborn.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

AMONGST the Patent specifications issued last week were two relating to the construction of power transmission cables and submarine signalling respectively.—Opposition has been entered to the grant of a Patent relating to telephone systems.—Patents for a high tension switch, the loading of telephonic transmission lines, an arc furnace and the Phillips commutator grinder expire this week after a full life. (Page 492.)

In an article on the effect of the war on the dynamo and motor industry, the directions in which greater activity may be developed are indicated and the general position is reviewed. (Page 493.)

THE feasibility of running a 460-volt D.C.-generator in parallel with several 230-volt machines is discussed in our "Questions and Answers" columns. (Page 494.)

A DESCRIPTION of the equipment of an up-to-date cinema theatre where electrical energy is generated on the premises and is also obtained from the single-phase supply mains, is given. (Page 495.)

OUR Trade Section contains an illustrated article on the Lemington lamp bulb factory, where the bulbs for Osram and Robertson lamps are blown; a description of some applications of electric drive in cider mills; and correspondence with regard to matters arising out of the war. (Pages 497 to 499.)

THE Engineering Standards Committee has issued a report dealing with the resistance of steel conductor rails and defines a new method for specifying these.—We summarise the revised regulations and bye-laws regarding the use of electric power on the L.C.C. Tramways.—A special report dealing with electric vehicles is to be drawn up by the South Shields Borough Electrical Engineer. (Page 496.)

THE Bamfield-Fanning Island cable has been cut by a German cruiser. (Page 496.)

CABLE is required at Warrington, Sunderland, Monmouth, and Torquay; generating plant, sub-station machinery and motors at Manchester; generating plant at Torquay, Southend, and Sunderland; electric supplies are required at Wolverhampton and Halifax; tramcars at Johannesburg; and telephone switchboards in Australia. (Page 500.)

THE first 5,000-kw. set in the new Bolton generating station has been started up.—There was a considerable increase in the net revenue at Aberdeen last year, and but for the present position of affairs a reduction in tariff would have been recommended.—Arc lamps are only to be lighted on Saturday nights at Sleaford in order to make the fullest use of the supply of carbons.—A 200-kw. generator ordered for the Stamford electricity works has been commandeered by the War Office. (Page 500.)

THE Mordey-Fricker Electricity Meter Co. is to be transferred to the British Insulated & Helsby Cables, Ltd.—A 6 per cent. dividend is recommended by the British Electric Transformer Co.—The Clyde Valley Electrical Power Co. reports a satisfactory year. (Page 500.)

THE proposed Bradford electrical exhibition next month is to be postponed. (Page 500.)

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

The 1914-15 session at the University of London (University College) begins on October 5th. Three-years' courses are given in mechanical, electrical, civil, and municipal engineering, and arrangements are made for degree and diploma courses, post-graduate work and research and special courses.

The Borough Polytechnic Institute, Borough Road, London, re-opens on September 21st. A four-years' course in electro-technics is given.

Other announcements will be found on pages vi and vii.

**Gone to the Army.**—We have received a postcard from our Paris contemporary, *La Lumière Electrique*, as follows:—"In answer to your letter of the 25th, we let you know that we have ceased to issue our paper since the beginning of the war, first of August, all us being gone to the army."—We are also informed that *l'Electricien* has suspended publication until the close of the war.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published September 3rd, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

18,170/13. **Cables for Power Transmission.** J. G. CUNLIFFE and R. G. CUNLIFFE. Each strand of the cable is coated with insulating enamel, and around the exterior of the cable is wound a similarly treated wire which serves as a protection. The whole may then be encased in a lead sheath. The advantages claimed are: higher permissible current density, low cost of manufacture, and comparatively high mechanical strength.

18,765/13. **Submarine Signalling.** R. A. FESSENDEN. The side of the ship is caused to vibrate rapidly so as to produce compressional waves similar to sound waves in air. A thin cylinder, rigidly attached to the ship side, forms the secondary of a transformer, and moves to and fro when the primary windings of the latter are excited by an alternating current. The compressional waves cause the sides of the receiving ship to vibrate in unison and induce currents in the windings of a similar transformer. These currents actuate a special form of telephone receiver. A microphone and a strong battery may also be used to excite the primary of the transformer on the sending ship for telephonic transmission. Four figures.

25,846/13. **Rotary Converter.** H. WADE (*D. A. Heyman*). The armature winding of the machine is connected to slip rings, and both the field and armature are first supplied with alternating current. When the machine has run up to synchronism, a switch is closed, either automatically or by hand, which arranges the connections so that a rectifying commutator on the armature shaft supplies both the field and the d.c. line with direct current, the armature still being supplied from the A.C. circuit. Four figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** STEINMANN [Mercury vapour lamps] 10,523/14.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** DAY [Couplings] 21,070/13; RAILING and TAYLOR [Conduit systems] 25,363/13; VAUGHAN [Insulating overhead wires] 25,790/13.

**Dynamos, Motors, and Transformers:** OTIS ELEVATOR Co. (*Otis Elevator Co.*) [Means for reversing motors] 4,211/14.

**Ignition:** KOPF [Sparking plug] 18,727/13.

**Incandescent Lamps:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Lamps] 18,448/13; GLADITZ [Manufacture of tungsten wire] 20,122/13.

**Switchgear, Fuses and Fittings:** MOND (*Maschinenfabrik Oerlikon*) [Controllers] 16,208/13; ART. GES. BROWN BOVERI ET CIE [Liquid resistances] 18,500/13; PRIOR & BUTTERWORTH & DICKINSON, LTD. [Switch-actuating apparatus] 19,141/13; B.T.-H. Co. and GIVEN [Motor control mechanism] 19,443/13; CREDENDA CONDUITS Co. and SUMMERHAYES [Resistance-wire supports] 26,704/13; NEWTON and NEWTON BROS. [Automatic starters] 8,178/14.

**Telephony and Telegraphy:** MATHYS (*Miller*) [Lock-out telephones] 18,609/13; CORWIN [Exchange systems] 19,305/13; HULTMAN [Automatic selector switches] 16,234/14.

**Miscellaneous:** YOULDON and YOULDON [Piano players] 15,733/13; SHENKER [Burglar alarms] 18,983/13; MAJOR, STEPHENS, and SMITH, MAJOR & STEPHENS, LTD. [Locks for lift gates] 21,050/13; B.T.-H. Co. [Ozone apparatus] 21,779/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Electrometallurgy and Electrochemistry:** A.E.G. [Welding machines] 16,126/14.

**Instruments and Meters:** LANDIS & GYR [Prepayment meters] 18,464/14; WILSON [Energy meters] 18,494/14.

**Switchgear, Fuses, and Fittings:** MAHONEY [Circuit interrupters] 16,318/14.

**Telephony and Telegraphy:** BRINKMANN [Contact apparatus for telephones] 17,863/14.

**Miscellaneous:** HAMMOND [Radio-dynamic control of gyroscopes] 18,408/14; DEL CASTILLO [Bell-ringing apparatus] 18,608/14.

### Opposition to Grant of Patents

14,524/13. **Telephone Systems.** W. AITKEN. Opposition has been entered to the grant of this Patent.

13,282/12. **Manufacture of Ductile Tungsten.** P. SCHWARZKOPF, S. BURGSTALLER, and WOLFRAM LAB., DR. J. P. SCHWARZKOPF. The grant of this Patent has been allowed by the Law Officer.

### Expiring and Expired Patents

The following Patents expire during the current week, after a *life of fourteen years*:-

16,130/00. **High Tension Switches.** B.T.-H. Co. (*E. M. Hewlett and W. Le R. Emmet*). The switch mechanism is suspended from a cast-iron frame which is bolted to the back of a slate or marble switchboard, and a handle at the front of the board operates the switch through levers. An oil holder is clamped in position on the underside of the frame, so as to enclose all the live parts of the switch in oil.

16,290/00. **Loading Telephone Lines.** G. A. CAMPBELL. The invention relates to the construction and arrangement of the coils used for the loading of long telephone lines. Copper wire is wound on a mandrel which is then withdrawn and a block of wood inserted at the centre of the coil. Two circular bundles of iron wire are introduced at opposite ends of the coil so that one end of each bundle touches the wooden block. The free ends of the bundles are then bent round the outside of the coil and bound in position, the whole being afterwards enclosed in a metal case. The claims also include for the provision of a series of gradually varying inductances at either or both ends of the transmission line to reduce "reflection" effects.

16,293/00. **Improved Arc Furnace.** J. IMRAY (*Soc. Elect. Metall. Française*). Where it is desired to prevent combination between the carbon electrodes of the furnace and the material which is being treated, the former are arranged vertically above the surface of the latter, so that two arcs in series are formed, the current flowing from one electrode, through the first arc, through the material and to the other electrode via the second arc. Arrangements are made to give the electrodes a vertical feed either automatically or by hand so as to maintain the arcs.

16,389/00. **Commutator Grinder.** J. PHILLIPS. An apparatus for trueing up the surface of commutators by an emery wheel, driven through a friction wheel and belting from the commutator which is being ground. The belt drives directly on to the spindle of the emery wheel, which is at the same time fed axially along the commutator by a worm and wormwheel. A longitudinal groove is cut on the worm, and when the grinding wheel reaches the end of its travel the worm spindle is turned so as to put the worm wheel out of mesh, thus allowing the grinding wheel carriage to be moved back ready for a fresh cut. An alternative method of feeding the grinder axially by the use of bevel wheels driving a crank and connecting rod is also described.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors and Transformers:** J. G. V. LANG [Dynamo and motor control] 11,974/07.

**Electrometallurgy and Electrochemistry:** H. RÖCHLING, J. SCHOENAWA, and W. RODENHAUSER [Furnace electrodes] 11,917/07.

**Ignition:** F. T. COTTON [Ignition device for gas-burners] 10,856/08.

**Incandescent Lamps:** A. JUST, F. HANAMANN, and VEREINIGTE ELECT. A.G. [Manufacture of tungsten filaments] 11,944/06; E. L. ELLIOTT [Lamp supports] 9,991/07; H. F. JOEL [Miners' lamps] 11,106/08, 9,693/09.

**Instruments and Meters:** EVERSHED & VIGNOLES and S. EVERSHED [Testing of insulation of lighting circuits] 11,509/03; CHAMBERLAIN & HOOKHAM and S. H. HOLDEN [Energy meters] 10,893/08.

**Switchgear, Fuses and Fittings:** T. VON ZWEIFBERGK [Motor control apparatus] 2,750/07; M. W. BRONDUM [Switch-operating mechanism] 10,715/08.

**Telephony and Telegraphy:** F. RITCHIE [Telautographic apparatus, i.e., for transmission of writing] 11,956/06.

**Miscellaneous:** M. A. ADAMS (*W. E. D. Stokes*) [Control of hydraulic lifts] 11,645/04.

## THE EFFECT OF THE WAR ON THE DYNAMO AND MOTOR INDUSTRY \*

THE effect which the war has had upon the manufacturers of dynamos and motors in this country is of a complex character. That the ultimate result will be greatly beneficial there is no room to doubt, and, in fact, the improvement is already being felt by some firms; others, however, are meeting difficulties which are an inevitable result of the "tightness" of money, and deriving only limited advantage from the transfer of orders to them of plant previously ordered abroad. Before going further, we may at once dispel the illusion that a large volume of orders from municipal corporations for electrical machinery has been placed on the Continent during the past few months and has now to be transferred to British firms. There are a few cases of this, notably that of the 5000-kw. turbine and alternator which was given to the Bergmann works in Berlin by the Bradford Corporation and has now been transferred to the British Westinghouse Company, but, taken as a whole, the municipal orders for German generating plant have been few during the past twelve months, and the gain in this direction is therefore small. It is probable also that, in the aggregate, the municipal orders for new generating plant will be less than usual this autumn, as the new lighting installations will be fewer in number and the power load will not increase at the same rate as during the past few years; manufacturers will largely rest content with their present methods of works driving rather than incur fresh capital expenditure. One may reasonably expect, it is true, that a fair number of new works will be established and new ones extended to take up manufactures in various trades which have hitherto been largely in German hands, but although the electrical installations for these will certainly entail the purchase of electric motors, &c., during the next few months, the actual load will probably not be sufficient to counteract the drop due to other causes until after the winter peak is over, so that it will not require the immediate erection of additional generating plant in the stations. There are, fortunately, some exceptions, however, notably that of Manchester, the building of whose new electricity works should shortly be commenced; meantime, as will be seen in another column, the electricity committee has just received sanction for a loan of £67,400, £29,400 of which is allocated to extensions at the Stuart Street power house, and the remainder is for sub-stations and the purchase of motors for hire.

Motors and generating plant for independent generating stations should shortly be in considerable demand, and, in fact, we believe that several useful orders are being placed already to meet unfulfilled orders placed with German firms or their agents before the war. In this connection we make no excuse for returning to the detailed figures for Germany's exports of electrical machinery during last year, which we published in our issue of August 13th. No less than 183,842 motors and generators were exported from Germany during 1913. Of these, on a rough estimate, between 14,000 and 15,000 were sent to Great Britain, the majority being motors of small and medium size. A big diminution in the country's requirements will still mean a large number of extra orders for British manufacturers. But this is not all, the article from which we quote shows that there will be good markets in British South Africa, Russia, Belgium, Scandinavia, Spain, Japan, China, and South America in which Germany has

hitherto delivered largely. In Australia there is also a growing market in which German competition has developed to a considerable extent comparatively recently.

For some reason, whether on account of price or experience, a German company has been particularly successful in the electrical equipment of mines in this country. Several British firms have, of course, also specialised in this class of plant, and others are certainly in a position to do so. The principle of the explosion-proof motor is now well understood and its design is not difficult; moreover, it must not be forgotten that a very large proportion of the electrical machinery and apparatus for mines is required on the surface or in positions where explosion-proof apparatus is not specified. Coal-mining continues with unabated vigour, and this field is worth cultivating.

Having referred to some of the directions in which increased business may be sought, to make up for the inevitable diminution due to the general industrial position, we may refer to some of the difficulties with which manufacturers of dynamos and motors have to contend. These are practically the same as those of all other manufacturers at present. Money is not changing hands as it does when trade is good; and also the part of the raw material which has to be imported has, of course, been held back in numbers of cases. The raw material for the electrical manufacturer—iron and steel, wire and cable, &c., is, for the greater part, not directly imported—although much of the raw material from which this is made is necessarily of foreign origin. Under present conditions the importer or supplier of this material demands cash payments, and the result is that cash payments are asked from the dynamo and motor manufacturer as well, and the position is temporarily one which discourages the manufacturer from seeking fresh orders. This is already improving, however, and it cannot be long before the conditions are normal. A slight difficulty with which the dynamo and motor manufacturer has to contend is that he has been in the habit of buying some of his insulating materials and some other small parts from abroad—in most cases probably indirectly, through agents in England. This is, however, a small matter which will also adjust itself; all this stuff can be manufactured here. Lastly, there is the fact that large numbers of workmen and members of the staff have left to "join." That the proportion in some cases is large is a matter for congratulation, but it is no reason for a slackening of speed in the order-getting department. One already hears of some works being run at reduced time, so, for the present, there are workmen enough. Until every man who should join the colours has done so, and every man remaining at home is employed and working on overtime, no effort should be spared to keep works going at their maximum speed of production. The increase of trade after the war will again give employment to those who come back after serving their country as well as to those who have filled their places during their absence.

---

**Electrolytic Lightning Arresters.**—In a Paper read before the American Institute of Electrical Engineers, Mr. E. E. F. Creighton discussed the status of the aluminium cell lightning arrester. Dr. Steinmetz contributed some valuable information regarding the form of wave front of a lightning surge. The chief point brought out by the Paper and the discussion was that we do not at present clearly understand the nature of lightning flashes, and therefore cannot yet design an arrester which will be efficient in all circumstances. There are definite limits both to the rate of maximum current discharge and of energy absorption for any arrester, and if these are exceeded, damage will result.

\* Previous articles, "Germany's £14,500 Export Trade Analysed," "An Appeal to Manufacturers," "The Effect of the War on the Electric Lamp Industry," "Effect of the War on Street Lighting," and "Openings for the Extension of our Electrical Export Trade" appeared in our issues of August 13th, 20th and 27th, and September 3rd.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,408.

It is desired to run two rotary-converters in parallel from an A.C. generator with a single winding. An essential part of the scheme being that each rotary can be started or stopped independently of the other. As part of the generator output is required for transmission purposes, two separate windings, one for each rotary, cannot be considered. The D.C. output is required for lighting or traction. Would it be necessary to use a transformer or reactance with one rotary, or would it be possible to run the rotaries in parallel on both A.C. and D.C. ends? If the latter scheme is undesirable, as seems to be the case, what are the reasons?—"ROTARY."

(Replies must be received not later than first post Thursday, September 17th.)

### ANSWERS TO No. 1,406.

Several D.C. compound-wound, 230-volt generators varying in size from 250 to 750 kw., run in parallel on the bus-bars to supply works' load, all series windings being connected to an equaliser bus-bar. There is a shortage of power, and it is desired to make use of a 1,150 kw. 460 volt compound-wound interpole generator. Could this machine be made to run in parallel on the 230-volt bus-bars, and if so, what current can be taken from it. State what alteration, if any, will have to be made.—DOUBTFUL.

The first award (10s.) is given to "ASTATIC," who writes as follows:—

It is not an infrequent practice to run generators at half their normal voltage in parallel with other generators of this voltage. Fig. 1 is a diagrammatic sketch of a four-pole, short-shunt, compound-wound interpole generator connected to an equalising bar. In this sketch *A* is an ammeter, *V* a voltmeter, *ES* the equalising switch, *MS* the main switch, and *R* is the shunt rheostat. The series and interpole coils are indicated by large and small circles respectively, the polarity of each coil is shown, and the shunt circuit is indicated by the dotted lines. It will be noticed that two series coils are in series with two interpole coils, and that these four coils are in parallel with the remaining four coils. This is a method adopted in the design of large multipolar generators, the object being to reduce the drop of voltage in these coils to a minimum. We will suppose that this generator meets the details in "Doubtful's" question, i.e., it is 460 volts with a capacity of 1150-kw. or 2,500 amperes.

In desiring to run this generator at 230 volts we must not lose sight of the fact that we cannot with safety take more than 2,500 amperes from the armature, and to take this amount of current it is necessary that the fields should be equally as strong as though the machine was generating 460 volts.

From this it is apparent that the case cannot be met by reducing the speed of the dynamo engine to generate 230 volts, because the current through the shunt fields would only be half the normal quantity. The result is that the field strength would be reduced by half, the field distortion would

be very great, and although an interpole generator, the brushes would have to be continually moved to pick up the neutral position with each variation of the load.

It is therefore obvious that if the field strength is to

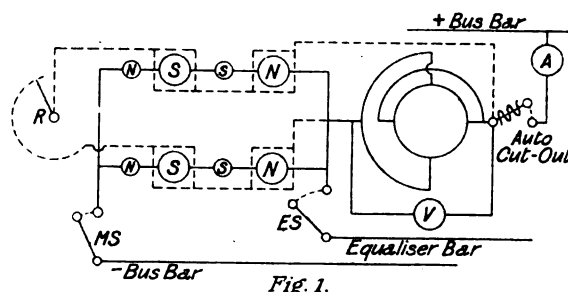

Fig. 1.

Fig. 2.

remain constant, alterations have to be made to the shunt winding, and this is done in the manner shown in Fig. 2.

In this diagram the shunt winding is shown in two halves, and the two halves are connected in parallel across the armature terminals. From this it will be seen that if the generator is run up to 230 volts, the shunt field will be up to its normal strength, and the only thing necessary is to increase the carrying capacity of the shunt regulator, as it will now be carrying twice its normal current.

The machine may now be placed in parallel with the other machines in the following manner:—Run the dynamo engine up to 70 per cent. of its ordinary speed, and adjust the shunt regulator until the voltmeter indicates a voltage slightly below the voltage of the machines under load. Then close the equaliser switch, then the main switches, and adjust the shunt regulator until the machine is taking its share of the load. The disadvantage of using machines in this manner is that the output of the machine in kilowatts is reduced by half. It is a much better policy, where it is possible, to run the machine at its full voltage, and connect up the load on a three-wire system.

The second award (5s.) is made to "R. W. J." for the following reply:—

There is no simple and efficient method of converting the 460-volt machine to supply the 230-volt bus-bars direct. Theoretically it could be done by (a) weakening the field by inserting resistance, but sparking and bad regulation would result from working on the unsaturated and unstable portion

Fig. 3.

Fig. 4.

of the magnetisation curve; (b) reducing the speed of the generator. This again produces bad commutation owing to the altered frequency of the same, not to mention difficulties of engine governing and bad efficiency through conditions other than those for which the machine is designed. Alteration of armature conductors is not simple, and therefore assumed out of the question. Even if the armature were re-wound, the two halves of the field put in parallel and any other arrangement made for generating at 230 volts the machine would only give half-load, since brushes, commutator, &c., would only carry the same current (2,500 amps) as at

460 volts; therefore, the efficiency of both generator and engine would be low.

If the 460-volt machine is on hand, or circumstances make it sufficiently desirable to use it, the best way would be to convert the system to three-wire, with 230-volt machines on the inners and the 460-volt across the outers, thus allowing all machines to work normally. In addition to the usual advantages of three-wire distribution, the conditions are very favourable, since a works load allows of convenient grouping and balancing by means of the present sets.

The greater portion of the present installation may need no alteration if the extensions can be balanced against it. Reference to the general diagram shows a new equaliser bar,

and also an earthed neutral bar, which may, of course, be smaller than the main bars.

By adjusting the compounding of the various machines a wide range of regulation and operation can be obtained, and although the foregoing is merely an outline, the advantages and possibilities of the scheme are obvious.

#### ANSWERS TO No. 1,405.

Mr. F. R. C. Rouse writes objecting to "M.'s" reply to this question, to which the second award was given. We admit that "M.'s" solution is not correct,—in fact he practically admitted it himself,—but it had the merit of being a good attempt and interesting. "F. R. C. R.'s" answer, to which the first award was given, was correct.

## THE ELECTRICAL EQUIPMENT OF AN UP-TO-DATE CINEMA THEATRE

A FINE example of an up-to-date cinema equipment is to be found in the two theatres which constitute the establishment known as the "Blue Hall," King Street, Hammersmith. The original Blue Hall, which has a seating capacity of 1,300, was opened in December, 1912, and is provided with its own suction gas-driven generating plant. Its success was so great that in order to relieve overcrowding another even larger hall (seating 1,700) was soon afterwards built at the back. Owing to the position of the engine-room precluding extensions of plant, and to the short time that was available (for the new hall was built and opened complete in three months) it was not practicable to have an independent source of supply, so that in this case current is taken from the mains of the Hammersmith Borough Council. Thus the whole establishment is of considerable engineering interest, embodying, as it does, arrangements for making use of independent and outside supply. It is not possible to make a reliable comparison of costs between the two methods, as the load-factor of the two halls is very different, the newer one taking only the "peak" of the business in the evening, while the older hall is open a much larger part of the day. There is no harm in remarking, however, that the proprietors express themselves quite satisfied with their own generating plant on the score of economy. As the engines are independent of the town gas supply, it is possible to use gas from the ordinary low-pressure mains as a stand-by for auditorium lighting, &c., while for a stand-by for some of the external arc lighting, high-pressure gas coming from an entirely different gas-works is used.

The engine-room supplying the original hall is in the rear of these premises, between them and the front of the new hall, and, as will be seen, great and successful precautions have been taken to avoid nuisance from noise, smell, or vibration; a very important matter in a residential neighbourhood. There are two continuous-current A.E.G. dynamos, each being driven by a "National" gas-engine. One is rated at 176 amperes and the other at 265 amperes at 110 volts. As a general rule the smaller machine supplies the projectors and auditorium lights during the daytime, and the large set is started up in the evening for the outside arcs, signs, and decorative lighting. In the event of a breakdown to one machine, the exterior lighting is cut down, when even the smaller machine can keep the projectors and the necessary lighting going. Such a contingency has, however, not yet arisen, and during the time the plant has been running it has not been found necessary to rely upon one machine. The sets are not run in parallel, but each has its own bus-bar on the switchboard, to which any of the following four circuits can be connected by double-throw change-over switches: projectors, inside lighting, outside arcs and decorative lighting, signs. The normal load with the usual lights on amounts to about 150 amperes for the small machine and 200 amperes for the larger one. In view of the limited nature of the attendance, this separate circuit arrangement was considered more advisable than parallel running. The engine-room contains the distributing board for the outside arc circuits, as well as the main board. These arcs are mostly along the roadway leading to the new hall, which is brilliantly illuminated by flame arcs on street-lighting posts. The "National" gas producer is in a room adjoining the engine-room, and is in a single unit for both engines. Anthracite fuel is used, and there is absolutely no smell in the producer room. Particular care has been taken in the silencing of the exhaust of the engines. Six pits are provided, three for each engine, and the gas passes through specially-arranged perforated metal plates and shingle ballast. This form of silencer, which is very efficient, was designed specially

for the job. In order to preclude further all possibility of annoyance from the plant, a deodorising equipment is provided for the effluent from the gas producer, which is passed into a large tank, where it is thoroughly mixed with a permanganate of potash solution, and as an additional precaution is only passed into the drains at night. Vibration is minimised by the mounting of both engines on "Mascolite" anti-vibration foundations. The result of all these precautions is that it is impossible to tell, when in the main or adjoining buildings, whether the plant is running or not.

From the engine-room cables are taken to the intake chamber of the older hall, where D.P. switches are provided for all four circuits with ironclad fuses. The whole of the switches for the auditorium lights are also in this chamber, an arrangement distinctly preferable to the use of secret switches about the auditorium itself. Some of the outside lighting is also controlled from this point, including signs and decorative lighting. The excellent precaution is taken of providing an emergency switch short-circuiting the entire interior lighting distribution board, so that the auditorium can be flooded with light instantly when required.

The main illumination of the auditorium is by indirect cornice lighting, giving a very restful effect, and as this is always turned up gradually through a dimmer, all shock to the eyes is avoided when the lights are put on between pictures. The lamps are of the metal-filament tubular pattern in porcelain trough fittings which plug together to form a continuous strip not requiring any wiring. Each unit of 25 c.p. is 9 in. in length, and there are in all more than 500 lamps. The side lighting, which is always on, is in special shaded fittings, throwing light practically only on the floor, and is alternately gas and electric, the fittings being made as much alike as possible. There are on each side of the proscenium, in addition to the number signs, electric clocks with dials illuminated from the back, which are lit up at the same time as the main lighting between pictures. These are part of a set of "Synchronome" clocks, controlled by a master controlling clock in the vestibule. It may be mentioned here that all the external wiring is in substantial galvanised pipes, and that screwed barrel conduit of the best class is employed for all interior wiring.

The operating box above the gallery at the back is spacious, cool, and airy, and contains a pair of "Simplex" cinematograph projectors and a slide lantern. Hand-regulated arcs, taking 50 to 60 amperes are used, and the film mechanism is driven by small electric motors. A switch panel contains the change-over switch putting one or other projector in action and other necessary gear. The regulating and steady-ing resistances are behind this board. The dimmer for the main lighting, which is of the metallic type, is also placed in the operating box, and a switch is provided by which this can be short-circuited if required. The ventilation of the hall is taken care of by a pair of 48-in. Blackmann electric fans.

The new hall, which is of rather larger size than the older one, takes its supply, as has already been remarked, from the single-phase mains of the Hammersmith Borough Council. This is converted to continuous-current for the projectors by motor-generators in the intake room. Two of these are installed, only one of which is used at a time, while the other forms a stand-by. Each set consists of a continuous-current A.E.G. dynamo rated at 125 amperes, driven by a slip-ring type induction motor. The sets are mounted on "Mascolite" anti-vibration foundations, and the bed-plates are not bolted down in any way. The starting board is equipped with drum-type starters, and change-over switches put one or other of the generators on to the projector circuit. In the same

chamber are placed the main intake ironclad switches and fuses, meters, &c., and the main distributing board for the interior lighting, which is, of course, taken direct off the main. This consists of a collection of ironclad switches and fuses mounted on a teak board. The lighting circuits are further sub-divided in another brick distributing chamber, where a fuse-board of the ordinary type is provided. The auditorium is similar to that in the older hall, as regards the cornice lighting and alternate gas and electric masked side lights, but there is in addition an extremely handsome semi-indirect corona fitting suspended in the centre of the ceiling, with sixty lamps throwing practically all their light up to the ceiling and most effective blue glass illuminated panels all round. This fitting was specially designed and made for the Blue Hall, and is a remarkably fine piece of work. A similar arrangement of illuminated clock dials is employed as at the other hall.

The equipment of the operating box is generally similar to that in the older hall, with two "Simplex" cinematograph projectors and one slide lantern. Practically the only difference, apart from the smaller resistances required, on account of the lower voltage of the projector circuits, is the improved form of dimmer employed. The switch arm of this is connected by a toggle joint arrangement of levers to a dash-pot in such a way that once past the dead centre a spring advances the arm slowly against the dash-pot and cuts out the resistance automatically. A single pull on a rope alongside any projector gives the initial movement, and the rate at which the resistance is cut out does not depend on the operator. Two 48-in. fans, similar to those in the older hall, are used, and the method of control is interesting. The London County Council regulations require that the starters must be within sight of the fans. Now, as it is inconvenient to send up to the roof every time the speed of the fans is to be regulated, a regulating rheostat is installed in the distributing chamber on the ground floor for each fan in series with the ordinary starters near the fans. By this means, when it is required to diminish the air current, the fans can be brought down to a very slow speed from downstairs. There is an "off" position on each regulator by which the fans can be stopped, but they cannot be started again, except from upstairs, owing to the action of the no-voltage release on the actual starters. All important points are connected together by Sterling inter-communication telephones. It is perhaps unnecessary to describe in detail the external lighting. Not only is there a liberal supply of flame-arc lamps, but there is some most effectively arranged decorative lighting and signs employing some 2,000 incandescent lamps, which draw attention in suitable and successful manner to this excellently equipped establishment.

In conclusion, we wish to express our thanks to Mr. James W. Barber, Consulting Engineer to the proprietors, who was responsible for the electrical arrangements, and personally explained the equipment to our representative.

### ELECTRIC TRACTION NOTES

A new Report (No. 68) has just been issued by the Engineering Standards Committee dealing with the "Method of Specifying Resistance of Steel Conductor Rails." As is pointed out in the Preface by Dr. R. T. Glazebrook, this Report will have considerable value inasmuch as it will help to remove ambiguity from specifications for work or materials, and thereby reduce both the cost of preparing tenders and the possibilities of dispute. The method selected by the Committee is to define the standard dimension in terms of length and weight per yard. The resistance of a steel conductor rail is to be expressed as the resistance in microhms at a temperature of 60° F. of a rail of the same material as the conductor rail in question, having a length of 1 yd. and a weight of 100 lb. The method of reducing observations made at temperatures other than 60° F. to the equivalent readings at that temperature is fully set forth, and tables of reduction factors to facilitate this are included. An Appendix contains reduction formulæ, so that previous values for the resistance of rails in terms of copper may be readily reduced to values in terms of the recommended standard.

The Revised Regulations and Bye-laws as regards electrical power on the London County Council Tramways have just been issued by the Board of Trade. In addition to some alterations of purely local interest, the following innovations of general interest may be noted. The use of a slot-rail "grip" brake has been made compulsory for cars working

over the High Street and Highgate Hill section of the line. The slipper brake, or other track brake, must be applied to all carriages travelling on falling gradients of 1 in 15 or steeper. The use of trailer carriages, which had previously been restricted to the conveyance of stores and sand to and from the depôts and the removal of disabled carriages, is now permissible on certain portions of the tramways for the conveyance of passengers, on such terms and conditions as may be approved by the Board of Trade, in accordance with the L.C.C. (Tramways and Improvements) Act, 1912.

The amount to be transferred to relief of rates from tramway profits at Sheffield for the year 1913-14 is £30,581, a record sum, and £2,081 more than the estimate. Before allocating this amount, however, the Tramways Committee has set aside £30,123 to renewals fund and £2,000 for a special purposes fund. At Newcastle the sum of £12,000 is to be transferred to relief of rates and £25,000 carried to appropriation account.

Mr. H. E. Ellis, Borough Electrical Engineer at South Shields, is preparing a special report on electric vehicles.

The Aberdeen Electricity Committee recommends that electrical energy be sold to the Tramways Department at 0.85d. per unit for the first 2,000,000 units, and 0.80d. per unit for subsequent units. This arrangement is to continue for five years.

The result of the year's trading to June 30th of the United Electric Car Co., Ltd., was an available balance of £14,654. A 5 per cent. dividend is recommended on the ordinary shares, £2,000 is added to reserve, and the balance of £2,154 carried forward.

**Telegraph Notes.**—The British Pacific cable between Bamfield (Vancouver) and the Island of Fanning has been cut, presumably by the German cruiser *Nürnberg*.—The Swedish and Danish Administrations have applied Article 8 of the Telegraph Convention, and the Swiss Government has prohibited telegrams to post or telegraph restante.—The Ottoman Government declines any responsibility or liability in connection with telegrams.

**The B.T.H. Co. and the War.**—The members of the staff and works of the British Thomson-Houston Co. are answering the call of their country in a whole-hearted manner. So keen is the patriotism of their employees that approximately 900 have answered the call. This represents over 50 per cent. of the eligible male adult employees. It is the company's intention to pay half wages to those of its employees who have enlisted, and wherever possible to reinstate returning employees in their former position on the cessation of hostilities. In those positions where fresh help has to be employed to keep the works going, no male candidates will be considered who are not over thirty-five years of age or who cannot give proof by showing H.M.S. certificate that they are medically unfit to enlist. Reserve and Territorial officers on the staff of the company have rejoined their respective units in the Navy, Lancashire Fusiliers, and the King's Horse, and it is noteworthy that one of the officers not being able to obtain his former commission has volunteered as a gunner in a Howitzer battery. Lord Kitchener has sent a letter through Major-General Rawlinson to the managing director expressing his appreciation of the company's attitude.

**Siemens Bros. & Co. and the War.**—More than 200 men employed by Siemens Bros. & Co. are now with the Colours, and, in addition to keeping all situations open, the firm is paying full wages to married men and half to single men. The cost to the firm is some £150 per week.

**The British Westinghouse Co. and the War.**—This Company has announced to its employees its desire that as many of them as possible should join the forces, and in order to provide for the welfare of dependents a substantial fund has been set aside. In addition, employment will be found for all those enlisting in the same or similar positions at the conclusion of the war.

**Special Constables.**—The full staff of the Marylebone Borough Council Electricity Department has been sworn in as special constables.

**The Manchester Engineers' Club Battalion.**—At an extraordinary general meeting of the Club members, held on Tuesday, it was decided to form a "Pals" battalion for Kitchener's Army, to be recruited from those engaged in the works and offices of engineering concerns. A special committee was appointed, consisting of Messrs. Daniel Adamson, H. T. Wilkinson, J. H. Stubbs, E. Simon, S. L. Pearce, G. Hughes, W. T. Anderson, E. T. Morland Johnson, E. L. Hill, and Colonel Hollingworth. Every member of the Club is asked to induce his friends, staff, and employees to join, and to send their names as quickly as possible to E. L. Hill, Esq., The Engineers' Club, Albert Square, Manchester, with the following particulars:—Name in full; age; address; married or single; if married, number of children under 16 years of age; occupation; name of employer; previous training, if any, in the Forces of the Crown.

## "ELECTRICAL ENGINEERING" TRADE SECTION

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**THE "SAVING" LIGHT.**—We have received from the Edison & Swan Co., Ltd. (Ponders End, Middlesex), their latest production in advertising postcards. The design is entitled "The 'Saving' Light," and shows in the background a ship in distress, in the act of sending up a rocket signal. After describing a parabolic path, the rocket has burst and revealed the "Saving" light, in the shape of an Edison drawn-wire lamp. The company will be glad to send supplies of these cards upon application.

**FLOAT SWITCHES.**—A new list from the British Thomson-Houston Co. (Rugby and London), deals with their latest design of float switches, which are intended for use with motor-driven pumps, when it is desired to maintain a predetermined level of water in a tank or to limit the travel of the ram of a hydraulic accumulator. In the case of small power motors, these switches can be inserted in the main circuit, but for larger powers they are arranged to control the actuating coil circuit of an automatic starting rheostat. The switch is usually mounted on a wall adjacent to the tank containing the head of water to be controlled, and is operated from a copper float, through a chain and lever. In the case of a hydraulic accumulator, the chain and float are replaced by a rod which is attached to some moving part of the accumulator. Either alternating or direct current motors can be controlled by these switches.

**BELLS AND SYRENS.**—In a list recently issued by the Sterling Telephone & Electric Co. (210-212 Tottenham Court Road, W.) a large range of electrically driven bells and syrens are described. All the patterns are very substantially made, and have been designed to suit a variety of purposes, including tramway work, mine signalling, and for use in works and factories. Fire alarm apparatus and accessories are also dealt with.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**SHIP CLEANING APPARATUS.**—We are informed by the Submarine Motor Ship Cleaner Co. that the Admiralty have recently adopted their apparatus for removing the growths from the outsides of ships without the necessity of dry docking. This apparatus was fully described in an article in our issue of December 11th, 1913, page 705, and consists essentially of a water-tight motor driving a rotary brush. The pressure against the ship's side is maintained by a propeller in the back portion of the apparatus. A descriptive leaflet has been issued.

**MINE SIGNAL INDICATOR.**—Apropos of the recent regulations relating to mine signalling, Siemens Bros. & Co., Ltd. (Woolwich, London, S.E.), have introduced a new type of their Mine Signal Indicator, which automatically indicates the nature of the signal by means of a pointer moving over the face of the dial to the order given. A short article in our issue of October 2nd, 1913, gives some particulars of the way in which this operates.

### TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Bacup.**—The contract of Chas. Macintosh & Co. has been accepted for distributing mains.

**Manchester.**—A contract has been placed with the Mirrlees Watson Co. for the condensing plant for the new turbo-alternator recently ordered for Stuart Street station. The tender of W. T. Glover & Co. has also been accepted for cable. Other contracts recently given out by the Electricity Committee are as follows:—Carbon brushes, Le Carbone and Morgan Crucible Co.; flexible conductors, Chas. Macintosh & Co.; insulated wires, Liverpool Electric Cable Co.; binding and fuse wires, India-Rubber, Gutta-Percha Co.; fuse boxes, British Insulated & Helsby Cables, Ltd.; motors, Siemens Bros. Dynamo Works, Ltd., Electric Construction Co., Electromotors, Ltd., British Westinghouse Co., and E. Brooks; motor starters, Verity's, Ltd., Ferranti, Ltd., and G. Ellison; meters, Ferranti, Ltd., and Chamberlain & Hookham; incandescent lamps (metal filament), British Thomson-Houston

Co.; carbon-filament and radiator lamps, Siemens Bros. Dynamo Works, Ltd.; current and potential transformers, Ferranti, Ltd.

**Rotherham.**—A tender for meters has been placed with Chamberlain & Hookham.

A tender for 2½- and 5-ampere meters has also been placed with the Bastian Meter Co.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Although no official quotation is obtainable, the price of copper may be taken as from £59 to £60.

**Siemens Bros. Dynamo Works.**—Mr. C. Koettgen has tendered his resignation, which has been accepted, as a Director and as Managing Director of Siemens Bros. Dynamo Works, Ltd., and has no further connection with the Company.

**Bastian Meter Co.**—We are advised by the Bastian Meter Co., Ltd. (Bartholomew Works, Kentish Town, N.W.), that they hold large stocks of raw materials, and that they anticipate no trouble or delay in fulfilling all orders. The Bastian meter is manufactured throughout in England with British labour and British capital.

**Morley-Fricker Electricity Meter Co.**—The shareholders have passed a special resolution transferring the business of the company to the British Insulated & Helsby Cables, Ltd., for the sum of £8,500. The company is to be wound up voluntarily, and Mr. F. Miller, of 82 Victoria Street, is liquidator.

### APPOINTMENTS AND PERSONAL NOTES

Mr. Harvey Gooch, of Drake & Gorham, Ltd., has joined the Cameron Highlanders, and asks us to state that, owing to the short notice, he has been unable to say good-bye personally to all of his friends in the electrical industry.

An electrical engineer to take charge of train-lighting installations and the electric driving of locomotive shops is required by the South Indian Railway Co. Application to R. White, Consulting Engineer, 3 Victoria Street, London.

A temporary engineer in charge of the meter department is required by the Hammersmith Electricity Department. (See an advertisement on another page.)

A junior switchboard attendant is required at Swansea. Salary £70 rising to £100 per annum. (See an advertisement on another page.)

**Importation of Catalogues to South Africa.**—An alteration has been made in the South African Imports Tariff relating to catalogues or price lists of foreign firms addressed to importers, merchants, or manufacturers. Previously a 25 per cent. *ad valorem* duty or 2d. per lb., whichever is the higher, with a rebate to British goods of 3 per cent. has been charged, but in future these will be admitted duty free. This alteration in the law of the Union of South Africa was initiated by the British Electrical and Allied Manufacturers' Association and effected through the instrumentality of Sir R. Sothorn Holland, H.M. Trade Commissioner, Cape Town.

**Exhaust Steam Plant at a Coventry Colliery.**—In connection with this article in our last issue, describing the plant at the Coventry Colliery of the Warwickshire Coal Co., Messrs. Willans & Robinson, Ltd., inform us that they were the main contractors for the complete turbo-generators and condensing plant, and that the General Electric Co. were sub-contractors to them for the supply of the alternators. We much regret that this important fact should have been omitted by the correspondents who sent us the article.

**Dispute as to Ownership of Carbons.**—With reference to the note on this subject on page 489 of our last issue, the Beck Engineering Co. in the High Court on September 2nd applied to continue an Order obtained *ex parte* restraining the Foster Engineering Co., Ltd., their servants and agents until after Wednesday, September 2nd, from parting with or dealing in any way with the ten thousand Beck flame carbons which are the subject of the dispute. Mr. Justice Shearman, however, after hearing both parties, refused the application and discharged the Order already made.

## THE LEMINGTON LAMP BULB FACTORY

THE outbreak of war has brought into prominence the dependence of many industries and undertakings upon supplies from the Continent. It has also made conspicuous—though in a much happier way—those enterprises whose products have been wholly manufactured in Great Britain. Owing to the prevalence and persistence of foreign importation, it has been very difficult in many cases to maintain the policy of all-British manufacture. The companies which did this, in spite of the tidal waves of Continental competition, are now reaping the well-deserved reward.

Glass plays a very important part in electrical apparatus; it is an obvious essential in electric incandescent lamps, which

FIG. 1.—GENERAL VIEW OF THE WORKS, SHOWING THE "CONES" OR GLASS HOUSES.

are now produced in millions every year. For various reasons most makers of electric lamps in Great Britain have imported the bulbs from Germany or Austria, and have disregarded, as remote, any danger which this reliance upon foreign glassworks might entail.

Ten years ago, however, the General Electric Co. took steps to secure an independent British supply of lamp-bulbs, and after a careful survey of the situation it decided to acquire glassworks of its own. An opportunity presented itself in connection with glassworks at Lemington, Newcastle-on-Tyne. In taking over these works the General Electric Co. formed a subsidiary company, the Lemington Glassworks, Ltd., in which it holds a controlling interest. At the time

FIG. 2.—THE MIXING HOUSE.

of purchase the works possessed two glass-houses, but the equipment has been gradually extended until the number of glass-houses reached six. This development, we are informed, was not achieved without many difficulties. Glass-blowing is a highly skilled trade, and the Company found it necessary to train the labour it required for the special work of blowing the various bulbs required for incandescent lamps. This process occupied a considerable amount of time, and demanded an expenditure which appeared at the time to be

burdensome, in view of the continued importation of large quantities of bulbs at low prices. But in the face of all the difficulties the works grew steadily, and they are now giving continuous employment to about 250 workpeople.

The main purpose of the works has been, of course, to supply bulbs to the Robertson Lamp Works (and later on the Osram Lamp Works), but we understand that the G.E.C. does not hesitate to go to the assistance of other electric lamp makers in this country. On several occasions, they tell us, when there has been a shortage of importation from the Continent, there would have been a serious famine in bulbs if the supply had not been available from the Lemington Glassworks. In the present critical state of things, with importation absolutely stopped, the G.E.C. has decided to continue this broad-minded policy. So far as the capacity of the works will permit—and subject, of course, to the demands of the Government—the needs of all electric lamp makers will be met. Moreover, arrangements are being made to extend the works as rapidly as possible. It is estimated

FIG. 3.—THE TUBE SHOP.

that the cessation of the foreign importation of glass offers an opportunity for the employment of from four to five times the number of people at present engaged in this section of the British glass industry.

A specific instance of the value of the works during the war crisis may be mentioned here. Soon after the outbreak of hostilities an urgent Government order was received by the Robertson Lamp Works for a special type of electric lamp. The glass for this type had previously been obtained from the Continent, but the Lemington Glass Works were able to produce the necessary bulbs so quickly that within three days of the receipt of the order complete samples of the lamps were in the hands of the Government Department concerned. These samples were approved, and the order to manufacture in quantities was at once put in hand. Even under normal conditions, the execution of such an order would have occupied six weeks if Continental sources had been chosen.

The accompanying pictures of the Lemington Glass Works are from photographs taken at the end of last month.

We are asked to add that the Lemington Glass Works are open to inspection by anyone who is sufficiently interested to write for permission to visit them. Inquiries should be addressed to Chris. Wilson, Esq., Brook Green Works, Hammersmith, W.

**"London Fair and Market."**—An exhibition bearing this name is being promoted by the International Trade Exhibition, Ltd. (Broad Street House, New Broad Street), who, it will be remembered, were organisers of the last two Electrical Exhibitions at Manchester and Olympia (London) respectively. The date will be March or April, 1916, the exhibition will be at the Agricultural Hall, and will be exclusively for manufacturers and wholesale houses (no German or Austrian goods admitted), and the whole of the gate money will be handed over to one of the existing public funds for the benefit of the dependants of soldiers and sailors who have fallen in the war.

**Competition with German and Austrian Trade.**—The Commercial Intelligence Branch of the Board of Trade at 73 Basinghall Street, E.C., ask us to announce again that they are desirous of hearing from firms who are prepared to send to them samples or catalogues of German and Austrian or Hungarian goods which have competed with British products at home or abroad.

## ELECTRICITY IN CIDER MILLS

THE arguments in favour of the adoption of electric drive in breweries apply with even greater force to cider making, since the large quantities of steam required for heating purposes in the manufacture of malt liquors are not needed by cider makers, while much of the machinery used is of the same type in the two cases.

An interesting, and at the same time very unusual, installation is in operation at Messrs. Goodwin & Co.'s Cider Mills, Hereford. For the purpose of extracting the juice from the

FIG. 1.—200-YEAR-OLD STONE CIDER MILL AND HYDRAULIC PRESSES DRIVEN BY B.T.H. MOTORS.

fruit, two hydraulic presses and an old stone mill are employed, the latter, which is over 200 years old, consisting of a massive stone roller revolving in a circular trough, also of stone, in which the apples are placed. This mill is driven by the B.T.H. electric motor shown, which also drives the pumps used in connection with the hydraulic presses, which can be seen in the background on Fig. 1, to the left of the old stone mill. This is believed to be the only example of an old stone cider mill still in use in the County of Herefordshire, and in any case the combination of this

FIG. 2.—HOIST IN CIDER MILL DRIVEN BY B.T.H. MOTOR.

200-year-old mill with a modern electric motor is certainly unique. The electric drive is also used at these works in connection with bottling and corking machines, aerating machines, &c.

Another Hereford cider mill which is electrically equipped is that of Messrs. H. P. Bulmer & Co., where, in addition to the advantages which always result from the introduction

of electric power, a remarkable saving of time has been effected by its means in connection with the emptying of the vats. The cider is fermented in huge vats, composed entirely of English oak, having a capacity of 50,000 gallons each. Before the adoption of electric power it was necessary to wait for a period of from two to three days after the removal of the fermented juice before the fumes had dispersed sufficiently to allow the men to enter the vats for the purpose of cleaning them. At the present time a small electrically-driven exhaust fan mounted on the top of each vat entirely removes the fumes in about a quarter of an hour. After fermentation the cider is bottled and corked, the bottles being then conveyed by means of the electrically-operated hoist, shown in Fig. 2, to the cellars where they are stored.

## CORRESPONDENCE

**The Varley Magnet Co., Ltd.**—Mr. C. Oliver, one of the Managing Directors, writes that an absolutely false report has been spread with regard to his firm. This report, which he has reason to attribute to a German competitor, states that the Company are dependent on Germany for their supply of raw material, and are unable to deliver their manufactured goods. In emphatically denying this, Mr. Oliver informs us that, as his Company use British raw materials in their manufactures, their business is now being carried on uninterruptedly, and is largely enhanced by a bulk of work which before the war came direct to this country from Germany. Their new factory, equipped with the most modern winding plant, is in a position to carry out any orders entrusted to them, and handle with particular energy work which has previously been manufactured outside this country. They are determined that this extra business shall lead to a permanent increase in the employment of British labour. As the coil-winding business in the past has largely been associated with German connections, they desire to emphasise that their Company without exception is English—in capital, directors, managers, clerks, and workpeople.

**The Sun Electrical Co.**—This Company asks us to state that, since its formation, it has been run entirely with English capital, with an English Board, under English management, and with a British staff. The whole of their own specialities and the greater proportion of their factored goods have been British throughout, and this policy will, in the future, be further extended to exclude everything of German manufacture.

**British-made Glassware.**—Mr. H. Hepworth Thompson, of Holophane, Ltd. (12 Carteret Street, Westminster, S.W.), writes us as follows: "In view of the stoppage to the importation of Continental-made glassware, I hope you will permit me to use your columns for the purpose of stating that Holophane is the only form of prismatic glass which is made in this country. Our works at Gateshead are well equipped for dealing with any demands which may be made upon them, and it is not anticipated that any difficulty will arise in regard to supplies of raw material. For these reasons, the prices of Holophane glassware will remain as before."

**War on German Trade.**—Under the *nom de plume*, "Common Sense," the (English) secretary of a company with works in England but with German-owned capital writes us: "As a nation, we have immense sums of money invested abroad, and therefore, on principle, we cannot quarrel with German investments here, especially when they are employed in manufacturing, and therefore have the effect of curtailing the importation of manufactured articles from Germany. The success of an industry (especially a comparatively new industry) depends upon the capital which it is able to attract. The British public have never given any real support to the electrical trade, and, backward as we are, our position would have been a thousand times worse had it not been for the financial support and enterprise of the foreigner. Doubtless there are many manufacturing concerns in England to-day who are supported partly by German capital, which they would be only too pleased to replace with British money if the British capitalist would come forward and divert into his own pockets this pipe line of gold in the form of dividends which, according to the daily Press, has been flowing to Germany. The Patent Act of 1907 was a direct discouragement to the importation of patented articles manufactured in Germany, and a direct encouragement to the employment of German capital in Great Britain, with the result that many articles which were previously imported are now being manufactured in British factories by British labour. If we are now going to turn round and drive foreign capital out, we are simply cutting off our nose to spite our face."

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Bacup.**—A supply of cable is required.

**Clatterbridge.**—Suction gas-driven generating plant and battery for infectious diseases hospital. Clerk, Wirral Joint Hospital Board, 54 Hamilton Street, Birkenhead. September 26th.

**India.**—The Amritsar (Punjab) municipality proposes to borrow £30,000 for an electric lighting scheme.

**Limerick.**—A 160-kw. Diesel oil engine and dynamo, and a motor-driven air-compressor are required. Borough Electrical Engineer. September 18th.

**Manchester.**—Sanction has been received from the L.G.B. for the borrowing of £67,400 for new plant. The amount is made up as follows:—Hired motors, £10,000; sub-stations, £28,000; Stuart Street extensions, £29,400.

**Monmouth.**—A loan of £1,800 for cable extensions is to be applied for.

**Portrush.**—It has been decided to adopt gas engines in preference to Diesel engines in connection with the electric supply scheme.

**Southend.**—A Local Government Board inquiry was held last week regarding an application for sanction to borrow £60,000 for extensions to the electricity undertaking.

**Sunderland.**—A L.G.B. inquiry was held last week concerning a loan of £50,000 for mains, and £13,600 for sub-station machinery and switchgear.

**Torquay.**—Sanction has been given to a loan of £5,000 for mains extensions. An inquiry will be held shortly with regard to a loan of £16,000 for new plant.

**Warrington.**—It is proposed to extend the electric supply mains into the Grappenhall district.

### Wiring

**London:** L.C.C.—215 wiring points at Giffard Street Elementary School, Caledonian Road, N. Chief Engineer. September 28. (See an advertisement on another page.)

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Bristol.**—Extensions at Stapleton infirmary.

**Bromley.**—New infirmary.

**Bury.**—Baths, Blackford Bridge.

**Manchester.**—Cinematograph theatre. Architect, H. A. Yearsley.—New works, Royton Street. Architect, S. Moss.—New police station at Irlam.

**Nantwich.**—Grammar school. Architect, H. Beswick, Newgate Street, Chester.

**Pontypridd.**—New fire station.

**Wrexham.**—Public hall and institute. Architects, Dickens, Lewis and Haynes, Shrewsbury.

**York.**—Offices for Weights and Measures Department, Friargate. City Engineer.

### Miscellaneous

**Australia.**—The Kalgoorlie Council requires a 5-ton wagon capable of being used for carrying road metal, for street-watering purposes, &c., at a speed of six miles per hour. The requirements of the Council, it is thought, will probably best be met by the wagon being arranged to haul trailers. Further particulars at 73 Basinghall Street, E.C.

The Deputy Postmaster-General, Brisbane, requires an automatic or semi-automatic switchboard and a common battery multiple switchboard. Further particulars, 73 Basinghall Street, E.C.

**Halifax.**—Three months' supply of electrical fittings for the Guardians. Clerk, Union Offices, Carlton Street.

**London:** St. Pancras.—Electric lift. Town Clerk. September 21st.

**South Africa.**—Ten single-truck double-decked cars are required by the Johannesburg municipality. Further particulars at 73 Basinghall Street, E.C.

**Wolverhampton.**—Twelve months' supply of electrical fittings for the Guardians. Clerk, Poor Law Offices. September 15th.

## LOCAL NOTES

**Aberdeen:** *Considerable Increase in Revenue.*—There was the considerable increase of £4,252 in the revenue of the electricity undertaking last year, compared with the previous twelve months, and a reduction in working expenses of £111. This result has been obtained notwithstanding coal has cost 1s. 4d. per ton more than in 1912-13. After meeting capital charges there was a balance of £4,960, which has been placed to reserve fund. Mr. J. A. Bell, the City Electrical Engineer, concludes his report by stating that under ordinary circumstances he would have proposed a rearrangement of tariffs, but in view of the present unsettled state of trade, which has already affected the output, he recommends that the existing scale of charges remain in force at least for the first six months of 1914-15.

**Bolton:** *New Electricity Works.*—The first generating set at the new Back-o'-th'-Bank electricity works was put into operation on the 3rd inst. The set has a capacity of 5,000 kw. The original plans for the works were got out under the direction of Mr. A. A. Day, when he was Borough Electrical Engineer some eighteen months ago, and they were formally opened last week. The Chairman of the Electricity Committee paid a tribute to the subsequent work done by Mr. W. J. Wood and his staff. The official opening will take place on some later date, and in the meantime further additions will be made to the equipment.

**Bombay:** *Street Lighting.*—The electric supply and gas companies are to carry out experiments in order to decide the comparative merits of gas and electric lighting.

**Malvern:** *Extension of Area.*—A canvass is being carried out in West Malvern in order to assist the Electric Lighting Committee to come to a decision as to a proposal to extend the mains into this district.

**Midhurst:** *Overhead Wires.*—The promoters of the Midhurst Electric Lighting Order, 1914, have approached the Council with regard to the formation of a company to carry the Order into effect, and also asking for permission to erect overhead wires. It is pointed out, however, that the capital cost of underground wires would render the scheme prohibitive, and that the financial success of it depends upon using overhead wires practically throughout the district, with the exception of certain thoroughfares in Midhurst. The necessary permission has been given.

**St. Anne's-on-Sea:** *Electricity Accounts.*—The accounts of the electricity undertaking to March 31st, 1914, show a net surplus of £1,163, of which £448 has been transferred to relief of rates, £217 has been placed to reserve, and £273 to the meters fund, the remainder being disposed of in other small items. The gross revenue was slightly less than in the previous year, owing to reductions in the price for both traction and lighting.

**Slaford:** *Supply of Arc-Lamp Carbons.*—The Borough Electrical Engineer reports that there is a sufficient stock of carbons to last ten months if the arc lamps are only lighted on Saturday nights. It has been decided to adopt this course.

**Stamford:** *Generating Plant Commandeered.*—According to a local paper the Urban Electric Supply Co., who own the works in Stamford, had a 200-kw. generator ready for delivery at the outbreak of hostilities, but it was commandeered by the War Office. In connection with the scheme of extensions in hand the engine has now been installed and a new dynamo has been ordered.

**Contravention of Factory Act.**—The North Eastern Marine Engineering Co., Ltd., have been fined £50 and costs at Sunderland for a breach of the electrical regulations of the Factory and Workshop Act, 1901. On July 21st a workman received a fatal electric shock whilst turning on a switch which was not protected in accordance with the regulations. It was stated for the defence that the switch was put in ten years ago, and that there had been no previous accident through it. Furthermore, it was alleged that the factory inspector had never pointed out that it was dangerous.

**The Bradford Electrical Exhibition.**—The Sub-Committee of the Corporation, which has the arrangements for the proposed electrical exhibition next month in hand, have passed a resolution recommending that it be postponed for the present, and that the organisation of it be continued at the earliest favourable moment.

### SUMMARY

THE latest Government proclamation with regard to trading with the enemy (the more important passages of which we quote this week), gives considerable latitude, of which many people will not desire to avail themselves. (Page 502.)

THE street lighting and railway station lighting of London have been materially reduced as a preliminary step towards rendering difficult the identification of particular points by airships at night. (Page 502.)

A NEW electricity works is being finished at Bolton to supplement the supply from the old works, and one of the two 4,000 kw. turbo-alternators is ready to be put on load. We publish a description of the station with a sectional elevation. (Page 503.)

THE heat treatment of steel for the manufacture of permanent magnets is described in our "Questions and Answers" columns. Readers are asked to suggest the best arrangement of a network of barbed wire, charged at 8,000 volts for the protection of a town against assault. (Page 504.)

THE electricity supply to the Sheffield tramways is to be taken over by the electricity committee instead of being separately managed as heretofore. (Page 504.)

A DESCRIPTION of the manufacture of Mazda half-watt lamps appears on page 505.

AMONGST the Patent specifications issued last week, were two relating to the manufacture of metal filament

lamps.—Application has been made for the suspension of a Patent for a self-cleaning sparking plug, owned by an alien enemy. This is the first electrical patent to be dealt with under the new rules. (Page 506.)

TELEPHONIC communication is available for the first time between South Australia and Victoria. (Page 506.)

MR. SYDNEY BAYNES, of the St. Pancras Electricity works, sends us drawings of arc lamp globes and asks other lighting authorities using similar globes to communicate with him. (Page 507.)

A LETTER from the General Electric Co. explains the circumstances in which a large amount of the share capital of the Osram Lamp Works is held in Germany. We also publish a long letter relating to the capital and management of the British Thomson-Houston Co., and some communications from other firms. (Pages 507 and 508.)

THE Institutions of Electrical, Civil, and Mechanical Engineers have been asked to obtain 500 men for the Divisional Engineer Units and Signal Company of the recently formed Royal Naval Division. (Page 508.)

A BRITISH magneto for motor cars is described in our Trade Section. (Page 509.)

THE Sydney Corporation has placed a contract for a 5,000 kw. turbo-alternator with Willans & Robinson, and has granted exceptionally favourable terms of payment. This replaces a German order given some time ago. (Page 510.)

EXTENSIONS are contemplated as follows:—Ashton-under-Lyne (£42,000); Bristol (£42,000); Cleckheaton (£2,200); Sheffield (£5,080); Bolton (£1,463); Torquay (£16,500).—Extra high-tension switchgear, static transformers, and low-tension switchgear are required at Walsall; electrical fittings at Brighton and Warrington; and electric motors at Whitefield. (Page 510.)

THE report by Sir John Snell on the Southampton electricity undertaking is to be considered at a special meeting of the Council.—The Dover Corporation has definitely refused to consider a bulk supply offer by the South-east Kent Electric Power Co.—Electricity for street lighting is to displace gas at Rochester. (Page 510.)

### NOTICE.

**READERS OF "ELECTRICAL ENGINEERING"**  
who do not have their copies posted to them direct from the Publishers are particularly requested to communicate with us, if they do not obtain the paper regularly and punctually.

"Electrical Engineering" should be obtainable  
at all railway bookstalls.

THE KILOWATT PUBLISHING CO., LTD., Publishers,  
203-6, TEMPLE CHAMBERS, LONDON, E.C.

### TRADING WITH THE ENEMY

**T**HE issue of the Proclamation last week defining what is meant by trading with the enemy, makes it quite clear that much greater latitude is allowed by the Government than was at first thought. The main passages in the Proclamation are as follows:—

The expression "enemy" in this Proclamation means any person or body of persons of whatever nationality resident or carrying on business in the enemy country, but does not include persons of enemy nationality who are neither resident nor carrying on business in the enemy country. In the case of incorporated bodies, enemy character attaches only to those incorporated in an enemy country.

We do hereby accordingly warn all persons resident, carrying on business or being in Our Dominions—

Not to pay any sum of money to or for the benefit of an enemy.

Not directly or indirectly to supply to or for the use or benefit of, or obtain from, an enemy country or an enemy, any goods, wares or merchandise, nor directly or indirectly to supply to or for the use or benefit of, or obtain from any person any goods, wares or merchandise, for or by way of transmission to or from an enemy country or an enemy, nor directly or indirectly to trade in or carry any goods, wares or merchandise destined for or coming from an enemy country or an enemy.

Not to enter into any commercial, financial or other contract or obligation with or for the benefit of an enemy.

Provided always that where an enemy has a branch locally situated in British, allied or neutral territory, not being neutral territory in Europe, transactions by or with such branch shall not be treated as transactions by or with an enemy.

Nothing in this Proclamation shall be deemed to prohibit payments by or on account of enemies to persons resident, carrying on business or being in Our Dominions, if such payments arise out of transactions entered into before the outbreak of war or otherwise permitted.

This, it would appear, actually gives permission to buy from or sell to a German firm established in this country, if its business here is incorporated in the form of an English company, although it is a criminal offence for an employé of the firm to transmit money to Germany or Austria directly or indirectly.

But the things one may do are not necessarily the things one will do. No decently-minded man will now buy German-made goods from the English branch of a German firm instead of buying British-made goods from his fellow-countrymen. The fact that the goods were made and sent to this country before the outbreak of the war does not make any difference.

There is another problem, however, which is perhaps more difficult of solution. Many cases are arising in which the English branch of a German company has had contracts to execute abroad and has been unable to complete delivery of the plant and material owing to the outbreak of the war. The company is endeavouring to buy goods to make up the contract from British firms. Are they to supply them? It is an outlet for new British trade, but it assists the German competitor, who has obtained a foothold here, to retain his position in competition with British firms, and, moreover, the goods with which the German firm has been helped out may even go forward without any indication of the name of the actual maker. In our opinion, the furthest point to which a respectable firm should go in this direction is to accept a transfer of the part of the order in question by the customer himself—if that customer is not an alien enemy in the literal meaning of the term (not in the restricted definition of the Proclamation).

Another class of firm from which Englishmen should not buy are those which have established themselves here with German capital, primarily for the sale of German-made products, but have built a small works here as a "blind." Sometimes these works are very little more than repair shops, sometimes they are hardly better than packing sheds.

We come finally to a third case, to which many columns have been devoted recently in the daily Press. Several electrical firms in this country are working with German capital for the benefit of German shareholders, but have always been manufacturing the greater part

of their products for the British market in their own works in this country. At the present time they are an appreciable factor in keeping our industries at work and our workmen employed. People have been exhorted not to deal with them, and, in fact, it is now an open secret that the council of the British Electrical and Allied Manufacturers' Association are disposed to recommend a boycott of the firms in question, and are taking a referendum of the members of the Association on the matter. We propose to return to this branch of the subject next week.

Messrs. Dorman & Smith, Ltd. (Salford, Manchester) have sent the following letter to the Assistant Secretary of the Board of Trade. They are of opinion that the attitude they have taken up is the correct one, and will be glad to know that they have the support of all their British competitors.

DEAR SIR,—We are in receipt of your communication of the 12th inst., enclosing copy of the King's Proclamation of the 9th September, "Relating to Trading with the Enemy," and we further note that under clause 5 (sub-clause 7) of same, it would be a contravention of the law to supply goods for the use or benefit of an enemy.

We have before us at the moment the status of the A.E.G. Electrical Co., Ltd., and as we are informed that the bulk of the shares of this company are, or were quite recently, held in Germany, we have declined to continue any business relationship with this company, in compliance with the above clause 5 (sub-clause 7). We are, however, threatened with penalties by the A.E.G. Electrical Co., Ltd., for the non-execution of an order for which we had tendered, and we are asking for the support of our competitors in the attitude we have taken up.

Mr. W. Perren Maycock urges us to publish a weekly list of firms mainly or partly "enemy," either as regards management or shareholders. He desires to include as enemies, in this sense, any German or Austrian who has not been naturalised over ten years. We regret that we cannot accede to Mr. Maycock's request. The majority of our readers already know whether the firms with which they deal are German or not, and the general public has been already sufficiently well informed by the daily press.

### THE LIGHTS OF LONDON

**T**HE lights of London have been dim since last Thursday, not because of a shortage of arc-lamp carbons, nor for the purpose of economising fuel, but as a dress rehearsal to ascertain to what extent the identification of particular parts of the metropolis might be rendered more difficult to the enemy's airships if these were to raid the metropolis. In some places the arc lamps were extinguished altogether, in others alternate lamps were lighted, and in other cases the globes of both electric and gas lamps were partially obscured to absorb light rays in an upward direction. The lighting of the various glass-roofed railway stations was also diminished, and dull gas lamps were alight in place of arcs. It would not be to the public interest to give details of the various steps taken, but it is not inconceivable that further diminution in the street lighting would be deemed advisable in the event of a bomb-throwing raid by German Zeppelins being considered imminent.

### THE NEW POWER STATION AT BOLTON

**T**O cope with the continually increasing demand for electricity in the Bolton area, an additional power station is being erected at Back O' Th' Bank, a spot about a mile distant from the old station in Spa Road. Although the erection was only commenced on May 2nd, 1913, the work is now nearly completed, and one of the two 4,000-kw. turbo-alternators is ready to be put on load. The demands made upon the plant at Spa Road have gradually increased until it is working at its utmost capacity, and it is anticipated that the new station, in addition to materially relieving this stress, will enable considerable economies to be effected, owing to the adoption of modern labour-saving appliances and plant.

In choosing the site, care was taken to provide for obtaining adequate supplies of water and coal. The station is situated on the river Tonge, and three reservoirs have been constructed, having a total capacity of 2,000,000 gallons, and the arrangements permit the circulating water for the condensers to be drawn from and discharged into the reservoirs or the river as may

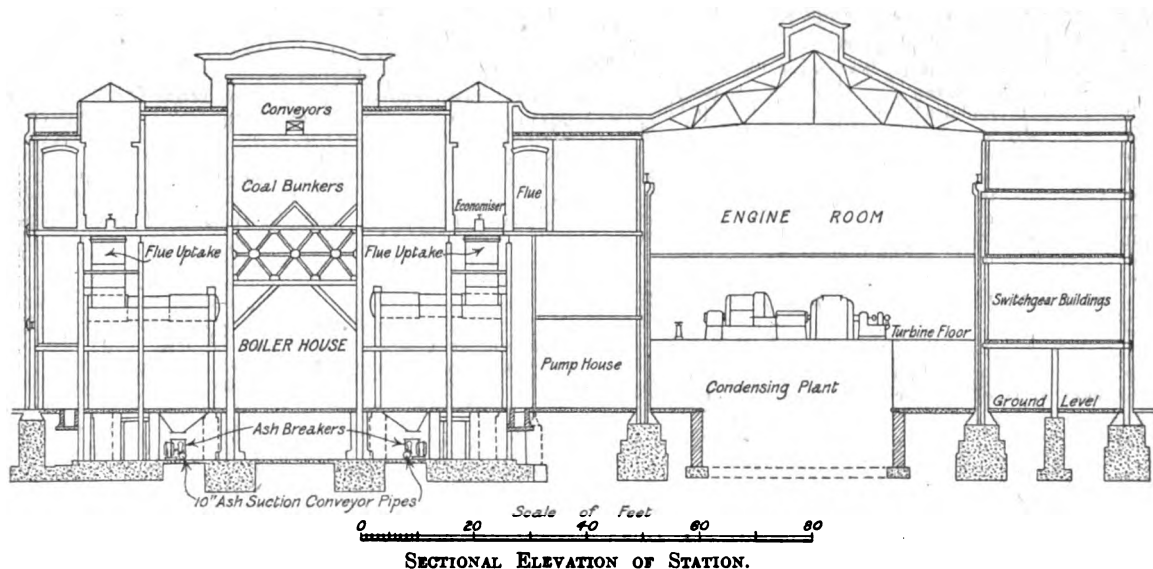

be required. A railway siding runs level with the top of the boiler house, and the coal is passed from the trucks into the main bunker by a rotary tippler, and a conveyor belt transports the coal from the main bunker to the boiler house bunkers which hold 50 tons over each boiler. From here it is led through Avery automatic weighers and into the stoker hoppers.

The boilers are four in number and are of the Babcock & Wilcox water tube type, capable of yielding 34,000 lbs. of steam per hour each, with chain grate stokers and Green's economisers. Natural draught is relied upon and is obtained by two chimneys, each 250 ft. high. The ash and clinker from each boiler are led into crushers from which they pass into a main suction pipe and are drawn into a closed suction chamber which can be emptied at intervals. The turbo-alternators are Musgrave-Dick, Kerr sets and are each rated at 4,000 kw. The supply is 3-phase, 6,500 volts, 50 cycles. The turbines exhaust directly into their own condensers which are each capable of dealing with 56,000 lbs. of steam per hour at 28 in. vacuum with the barometer at 30 in. and a circulating water temperature of 70°Fah. The auxiliary plant for the condensers is electrically driven throughout and, normally, is supplied from the 'bus bars through a

with a special insulating compound, "Floorine," which gives a pleasing finish to the surface, and a spiral staircase of steel provides a means of rapid communication between this floor and the switchgear cubicles in the room below. In passing, it may be of interest to note that all the concrete used for the floors and foundations of the station has been made from the sand and gravel excavated from the site, only a portion of which is occupied by the station as it now stands, as provision has been made for further extensions.

The lighting of the engine room has received careful consideration and it has finally been decided to adopt half-watt lamps, six of which will be required. At present, only two of these are fitted, and even now the illumination is found to be very satisfactory.

It will be remembered that all the coal used is automatically weighed before being burnt in the boiler furnaces. In addition to this, the steam consumption of each turbine is continuously measured and recorded by means of "Precision" water meters, by Alex. Wright & Son, arranged to measure the discharges from the respective air pumps. The cooling air for the alternators is supplied through Balcke dry air filters, and is led from the filters to the air ducts in the founda-

transformer, and in this connection a small substation equipment has been installed. A Brush motor-generator of 200 kw. capacity is used for charging a battery of "Chloride" cells which supply the continuous current necessary for energising the operating solenoids of the main switches which are of the remote control type. For starting the auxiliaries, the battery drives the motor generator, and the supply is taken from the A.C. side of the latter. The capacity of the battery is sufficient to enable it to run the auxiliaries for a considerable period in case of failure of supply. By this arrangement, the inconveniences attending the use of steam-driven auxiliaries are avoided, whilst at the same time the station is entirely independent of outside supply.

The switch gallery, which is adjacent to the engine room, has a remarkably neat appearance. The switches proper are arranged in the room below and, as has been stated above, are of the remote control type. Two sets of switchgear cubicles, of which the feeders are separate from the machines and arranged in groups, are controlled by group switches from the machine cubicles in the gallery above. Ample space has been left to allow for the addition of further sets, which it is anticipated will be needed as the station is extended. The Westinghouse Co. were contractors for the switchgear. The floor of the gallery is of concrete, covered

tions of the alternators in the usual manner. The cables are paper-insulated, lead-covered, and armoured, and are supplied by the British Insulated and Helsby Cables, Ltd.

The power distribution from the new station will be made to fit in, as far as possible, with the existing arrangements. As Bolton is essentially an industrial centre, the supply is mainly for power purposes in mills and factories. All power consumers obtain supply through transformers directly from the H.T. mains, the transformation being from 6,500 volts to 400 volts 3-phase. In addition, feeders are to be taken from the Back O' Th' Bank station to three substations at Duncan Street, Spa Road, and Bradshawgate. Of these, the second is the old power station, and the third has not yet been erected. As the demand upon the new station is likely to be very largely augmented in the future, a light steel temporary end has been used at one end of the building, so that further extensions may be easily carried out when required.

The striking feature of this installation is the attention which has been bestowed upon labour-saving appliances, the ideal which has been kept in mind being, as Mr. W. J. H. Wood, the electrical engineer of Bolton, put it, to run the station with the staff alone. We are indebted to Mr. Wood for allowing us to inspect this interesting and up-to-date station.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,409.

It is desired to erect around a city two miles in diameter a system of barbed wire charged at 3,000 volts as a protection against assault. Two three-phase generators, each capable of supplying 5,000 kw. continuously at this pressure, are available. Suggest the best design for the network, and the method of connection and arrangements of cut-outs, taking all the circumstances into consideration, including the necessity of automatically cutting out a section of the wire temporarily, if earthed, to save burning out the generators, and so cutting off the pressure from the whole network, and, if possible, the automatic replacement of cut wires.

(Replies must be received not later than first post Thursday, October 1st.)

### ANSWERS TO No. 1,407.

What is the best procedure for the hardening, tempering, or other heat treatment of steel for the manufacture of permanent magnets of great constancy for measuring instruments?

The first award (10s.) is given to "M." for the following reply:—

The steel used for making permanent magnets for instruments should be hardened by being heated to a temperature well above the recalcence point of the steel, and then quenched in water. To ensure good results it is essential that the steel should be heated perfectly uniformly, otherwise it will crack when plunged into the water. Also the temperature at which the steel is quenched must be correct for the particular brand of steel used.

In order to fulfil these two conditions it is usual to heat the magnet in a hot bath of lead or other molten material. A material which has come into use of recent years, and which is used by some of the leading instrument-makers, is common salt. The salt is heated in a crucible to a temperature of about 1,200°C., at which temperature the salt is quite liquid. The magnet to be hardened is immersed in the hot-bath for a short period, and, before quenching it, the pole tips are clamped in a gig to prevent it from warping in the cooling process.

The actual temperature of the magnet may be varied by varying the time of immersion in the hot-bath, as it is not necessary to leave it in the bath long enough to attain the maximum temperature. In order to ascertain the best temperature, an experiment should be made with several magnets, which can be hardened after being immersed for different periods. The magnets should then be magnetised under exactly the same conditions; the strongest magnet is picked out, and the remainder can then be treated in exactly the same way as this sample. It is always advisable to test a magnet occasionally, when hardening a batch, to see that they keep up to the standard, as the temperature of the bath may alter, and so necessitate an alteration in the period of immersion.

"AGATE," to whom the second award (5s.) is given, says:—

The forging of the magnet should be carried out at as low a temperature as is convenient, and with as little working as

possible. After forging, the material should be brought to a normal state by heating it to 900°C., cooling it to 750°C., and then, after keeping it at this temperature for a short time, cooling it off to atmospheric temperature. The magnet should then be hardened by raising it to 950°C. for not longer than five minutes, and then lowered to about 700°C., and quenched off at this temperature in brine or oil at a temperature under 20°C.

In the case of instrument magnets, there is not much to be gained by tempering them, but they should be "matured" by boiling or steaming them for ten or twelve hours, or by keeping them at a temperature of about 60°C. for twenty or more hours. The result is improved by letting them cool several times during the process.

For a complete record of technical research on permanent magnets the reader should refer to a lecture on "The Magnetism of Permanent Magnets," by Prof. S. P. Thompson, in the *Journal Inst. E.E.*, Vol. L., p. 80, 1912.

## ELECTRIC SUPPLY DEVELOPMENTS IN SHEFFIELD

### Amalgamation of Tramways and Lighting Departments

**A**N important report dealing with the supply of electrical energy to the tramways has been presented to the Corporation as the result of a conference between the Tramways and Electric Supply Committees.

Hitherto the tramways in Sheffield have been supplied from the Kelham Island power station, and originally the general supply for lighting and power was given from the Commercial Street station. Since then, of course, the Neepsend power house has been constructed and developed for the general supply, whilst certain additions have been made to the Kelham Island power station for tramway purposes. Latterly, however, a certain proportion of tramway energy has been taken from Neepsend, and the committees now recommend that it is not advisable to continue to develop the Kelham Island as a separate and isolated unit, but that power should be taken from Neepsend and dealt with by means of converting plant at Kelham Island, retaining the present generating plant at the latter, so that both power stations will be available. It is suggested that two 1,500 kw. converter sets be put down at Kelham Island as soon as possible, and that all current supplied from Neepsend be charged for at the rate of 0.8d. per unit measured at Kelham Island, on the D.C. side, the price to be subject to revision in three years.

In order to give full effect to this scheme it is further recommended that the capital account of the Kelham Island power station and the electrical equipment up to and including the section pillars be taken over by the electric supply department. This account stands to-day as follows:—Total capital, £318,064; payments to sinking fund, £96,914, leaving an outstanding capital charge of £221,150, plus the cost of the section pillars. Incidentally the benefit of all statutory provisions and powers to borrow money relating to Kelham Island and the electrical equipment up to and including the section pillars, is to be transferred to the electrical supply undertaking. Similarly all stores relating to the tramway power station and distribution system are to be transferred to the electric supply department at cost price or at a price to be agreed upon between the general managers of the respective undertakings, or failing agreement at a price to be fixed by the city treasurer.

The scheme involves, moreover, the transfer of the whole of the power station employees and also those engaged upon the distribution system to the electric supply department, and as we reported in our last issue, Mr. H. E. Yerbury, the present Electrical Engineer of the Tramways Department, is to be appointed Deputy General Manager and Engineer of the Electric Supply Undertaking, under Mr. S. E. Fedden, the present General Manager. The question of appointing a deputy to Mr. Fedden at a salary rising to £600 per annum, has been under consideration by the electric supply committee, but in view of the recommendation with regard to Mr. Yerbury this will not now be done, and, further, both Mr. Fedden and Mr. Yerbury have offered to accept the additional responsibilities imposed by the proposed transfer and amalgamation without an increase in salary at the present time, having regard to the national crisis. It is understood, however, that at an opportune time the salaries of these two officials should be reconsidered.

The report has been adopted by the City Council, subject to the necessary legal adjustments being made.

**The Association of Mining Electrical Engineers.**—In consequence of the abnormal state of the country, and the possibility of a large number of members being on active service, all arrangements in connection with the South Wales branch have been cancelled, and the visit of the Association to South Wales on October 2nd and 3rd has been postponed; but should circumstances permit, the meeting of the full Association will be held in the district some time next year.

## MANUFACTURE OF THE HALF-WATT LAMP

**L**AST Friday we responded to a pressing invitation to visit the lamp works of the British Thomson Houston Company at Rugby to convince ourselves, not only that half-watt lamps were being manufactured there, but that they were being manufactured on a commercial scale and at a rapid rate. For obvious reasons we are not permitted to describe the methods of manufacture in detail, but we have been allowed to publish a general outline of the methods of manufacture with—needless to say—some of the operations omitted. The several processes are being carried out

FILAMENT SHAPING AND MOUNTING.

simultaneously to prepare the various parts for assembly. First, there is the preparation of the filament until it is ready for mounting, and, secondly, the making of the stems, with their leading-in wires and the supports for the mica baffle plate which is held in the neck of the lamp, and the glass spider with the filament supports and the assembling of these. Then comes the mounting of the filament. Meantime, the glass bulbs are "tubulated," that is to say, pierced and fitted with a glass tube for exhausting. Then follows the sealing-in process, in which the stems with the filaments on them are sealed into the glass bulbs. Finally is the exhausting of the lamps, the filling with gas and sealing the pip.

We will commence with the treatment of the filament after it has been drawn, following the preparation of the metallic tungsten from the tungsten oxide and the subsequent drawing of the wire as carried on in the works. The filament of drawn tungsten wire is wound from bobbins by an extremely ingenious machine into the close helix, which is one of the now well-known characteristics of the half-watt lamp. An examination of one of these lamps shows that the helix is opened out at each of the supporting hooks, and this is done carefully and deliberately by the machine itself, and is not left to the operator who mounts the filaments. The filament is then shaped and made absolutely ready for mounting.

The supporting strip (a flat strip pressed to shape, with a bend to retain the mica baffle plate in the neck of the bulb) is cut out by a small machine worked by hand; the leading-in wire which makes connection with the filament, and the sealing-in wire which passes through the glass, are cut separately, and then joined together, the glass stem is prepared, as well as the spider for the filament supports, and the whole is then fixed together ready for the reception of the filament. The glass spider, which is one of the parts peculiar to the half-watt lamp, and is not employed in the

ordinary lamp, is made of special glass to withstand the great heat near the filament, and the machine for making this, although simple, is most ingenious, leaving very little to the skill of the operator. In fact, the keynote of the whole of the manufacture is that almost every one of the numerous processes has been brought down practically to a purely mechanical and continuous series of operations. The first and last operations are performed by hand, and the machine itself carries out the intermediate ones in the proper sequence with hardly any intervention by the operator in charge of the machine. Each stage in the manufacture of the various parts and in their gradual assembly to form the complete lamp is done by a different set of operators, every one of whom has become deft in the speedy and accurate handling of the machine and the material.

After the filaments have been mounted on the stems, the sealing-in process follows, and then the exhaustion and gas filling, as already mentioned. After this the lamps are tested and packed.

During our visit, while we were examining some of the glass-blowing, the fire bell suddenly sounded. The girls all left their work promptly and filed out of the various exits in a quiet and orderly manner, and the works were emptied in almost a minute. This fire-drill takes place, perhaps, once or twice a week, always at different times and unexpectedly, and there is no doubt that, if an actual fire occurred, the retreat would be as orderly and effective.

We have only mentioned the manufacture of the half-watt lamps during the course of this article, but in passing through the works we noticed some other comparatively new types of lamp in addition to the ordinary patterns which are turned out by the thousands. Automobile and various other types of battery lamps were being made, and it was interesting to see the small bulbs for these being blown in a machine by compressed air, instead of by the mouth. We also

SEALING-IN

noticed the new type of tubular or "Mazdalite" lamp for strip lighting, employing a length of spiralsed filament.

In fact, we passed a most interesting couple of hours at the works, and, as the British Thomson Houston Co. are inviting any of their customers, who are interested, to come down to see the manufacture of half-watt lamps themselves, we strongly advise our readers to take advantage of the offer. They will convince themselves that the British Thomson Houston Co. is in a position to supply the British market with British-made half-watt lamps of unsurpassed quality.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published September 10th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

*Names in italics indicate communicators of inventions from abroad.*

16,208/13. **Controller.** A. MOND. The handle of the controller is moved into any desired position, thus closing the circuit of an electro-magnet which turns the contact cylinder of the controller, through a pawl and ratchet wheel, step by step, until the cylinder is in the position corresponding to that of the controller handle. The circuit of the electro-magnet is then automatically broken. One figure.

18,448/13. **Incandescent Lamps.** B.T.-H. Co. (*G.E. Co., U.S.A.*). To increase the useful life of metallic filament lamps, nitrogen at a pressure of not less than 1/5 mm of mercury, and not more than 50 mm. for each sq. cm. of filament surface, is introduced into the bulb before sealing.

20,122/13. **Manufacture of Tungsten Wire.** C. GLADITZ. A method of tungsten wire of uniform tensile strength. The wire is *cold drawn*, and the cross-section is reduced by approximately 20 per cent. by each drawing operation. When the original cross-section has been reduced by about 50 per cent., the wire is wound on bobbins and is annealed by being passed through a heating chamber in an atmosphere of inert gas, where the temperature is gradually raised to 250°-400° C., and then gradually reduced to its initial value. The bobbins are placed on a conveyor belt which carries them at the required speed from one end of the furnace to the other, thus ensuring uniform treatment. Three figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** AYRTON [Holders for electrodes] 26,367/13; STAVE [Lamp globes] 29,425/13.

**Dynamos, Motors, and Transformers:** STORER [Dynamo-electric machines] 12,641/14.

**Electrometallurgy and Electrochemistry:** TANTON and AYMARD [Electrolytic recovery of metals] 19,669/13; QUENEAU [Furnaces] 10,061/14.

**Heating and Cooking:** PERRY and CREDENDA CONDUITS Co. [Cooking apparatus] 29,070/13; PATE and WOOD [Griller] 2,118/14.

**Incandescent Lamps:** MACKAY [Lamps] 1,252/14.

**Storage Batteries:** SVENSKA AKKUMULATOR AKTIEBOLAGET JUNGNER [Electrodes for alkaline accumulators] 1,062/14.

**Switchgear, Fuses and Fittings:** TUCKER [Switches] 19,388/13.

**Telephony and Telegraphy:** HULL [Party-line systems] 19,249/13; WESTERN ELECTRIC Co. (*Woodward*) [Impulse-producing mechanism] 19,752/13; THOMPSON [Automatic telegraph transmitters] 23,137/13; VAN KESTEREN [Telephone systems using reinforcing repeaters] 29,165/13; GRAHAM and SANFLEBEN [Telephone systems] 767/14; FRATELLI MARZI DI G. B. [Microphones] 2,624/14.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The *Financial News* announces that telephonic communication between South Australia and Victoria is available for the first time. The construction of the line has occupied about eighteen months, the total distance being 480 miles with no intermediate stations.

It is stated that the cutting of the Pacific cable, mentioned in our last issue, was done by a landing party from the German cruiser *Nürnberg*, which approached flying the French flag.—The Tokio-Guam cable failed on the 10th inst., and this is rather suggestive of cable-cutting.—Mr. Hobbouse declared in the House since our last issue that he is unable to permit the use of codes for commercial messages.—Telegrams to poste restante are again accepted for Swiss places since the 15th inst., but will only be delivered to addresses after identification.

Telegraphic communication with the Republic of Colombia is cut off, due, no doubt, to the failure of one of the T pieces from the main Panama-St. Elena cable. Meantime, arrange-

**Traction:** PRENTICE & STARRIE [Signalling systems] 19,019/13, 19,020/13.

**Miscellaneous:** CROSBEE, CROSBEE and ROGERS [Diaphragm horns] 25,795/13; O'KEENAN [Synchronising clocks] 2,924/14.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Incandescent Lamps:** WOLFRAM LAMPEN AKT.-GES. [Manufacture of ductile alloys with high melting point] 29,980/13; A.E.G. [Lamps] 18,566/14.

**Instruments and Meters:** BESAG [D.C. meters] 17,768/14.

**Telephony and Telegraphy:** SEELAU [Telegraphone] 14,439/14; HEYLAND [High-frequency generators] 17,331/14.

**Miscellaneous:** SIGNAL GES. [Device for use with motors] 10,048/14; VULCAN MASCHINENFABRIK A.G. [Cooling electro-magnetic clutches] 17,455/14.

The following Amended Specification may now be obtained:—  
**Distributing Systems, Cables, Wires, &c.:** W. CROMPTON & Co., LTD. [Regenerative motor control systems] 6,806/13.

### Application for Suspension of Patent

7,617/10. **Sparking Plug.** L. PODSZUS (Berlin). In accordance with the recent Act relating to British Patents owned by alien enemies, application has been made by J. H. Meyer, of London, for the avoidance or suspension of the above Patent. It relates to a self-cleaning plug consisting of a hollow central electrode in conjunction with a cylindrical outer electrode. Air is drawn through the central electrode and is deflected so as to scour the ignition points, thus cooling and cleaning them thoroughly.

### Opposition to Grant of Patents

3,481/14. **Electric Hair Curlers.** M. LUDICKE. The right to the grant of this Patent has been surrendered.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** H. BECK and DEUTSCHE BECK-BOGENLAMPEN GES. [Improved A.C. electromagnet] 12,253/07.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** A.E.G. [Arrangement of winding-motors] 5,250/06; NEW IGNITION SYND., F. J. ROUSE and W. J. L. SANDY [Plug couplings] 11,610/08.

**Dynamos, Motors, and Transformers:** H. A. MAVOR and MAVOR & COULSON [Motors for ship propulsion] 12,072/07.

**Electrometallurgy and Electrochemistry:** M. RUTHENBERG [Arc furnaces] 12,507/09.

**Heating and Cooking:** G. COOPER, F. C. SHARP, and T. A. STEVENS [Immersion heater] 12,562/09.

**Ignition:** W. ROOS [Magnetos] 12,135/07; A. GIORGI [Ignition apparatus for gas burners] 12,470/09.

**Storage Batteries, &c.:** S. BENKÖ [Primary battery electrodes] 12,677/09.

**Switchgear, Fuses and Fittings:** J. DUGDILL [Combined ceiling rose and switch] 11,887/04; H. J. FISHER [Protective devices for electric machinery] 12,452/09.

ments have been made to send messages by wireless.—The deferred and week-end letter service has been suspended to South America until further notice.—The Ceuta-Tangier cable was restored on the 13th inst.

### PATENT LOUD SPEAKING TELEPHONES

COMPLETE INSTALLATIONS FOR

**WARSHIPS, MERCANTILE VESSELS,  
MINES, POWER STATIONS, ETC.**

Adopted by the British Admiralty, Foreign Governments,  
the Leading Shipping Companies, and as used in many  
Electrical Generating Stations.

**ALFRED GRAHAM & CO.,**  
ELECTRICAL ENGINEERS AND CONTRACTORS,  
ST. ANDREW'S WORKS, CROFTON PARK, LONDON.

## "ELECTRICAL ENGINEERING" TRADE SECTION

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**SMALL MOTORS.**—The latest catalogue to hand from the British Thomson-Houston Co. (Rugby) is devoted to continuous and alternating current motors of small power. Some interesting illustrations are included, showing the application of the motors to a number of different drives. The power of these motors ranges from  $1/50$  to  $\frac{1}{2}$  h.p., and they are suitable for either 110 or 220 volts. The A.C. motors are designed for a supply frequency of 50 cycles per sec. We understand, however, that the motors can be designed to meet exceptional conditions, providing the quantity required is sufficient to justify departure from the standard.

**INSULATED LAMP HOLDERS.**—Simplex Conduits, Ltd. (Garrison Lane, Birmingham), have issued a list dealing with insulated lamp holders which will take all enamelled iron shades having the standard  $1\frac{1}{2}$  in. opening.

**"ALL-BRITISH LAMPS."**—The Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlessex, and 123 and 125 Queen Victoria Street, E.C.) has issued a bold show card printed in black and red and measuring 32 inches by 20 inches, drawing attention to their "All-British" metal filament lamps.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**ELECTRIC TOOLS.**—A new electric tool catalogue to hand from the Consolidated Pneumatic Tool Co., Ltd. (9 Bridge Street, Westminster, S.W.), deals with "Duntley" drills, grinders, boring machines, hammers, blowers and sand-shakers, couplings for electric cables, &c. The tools are manufactured for both direct and alternating current, and some sizes are wound both for 400 volts to 600 direct and alternating current. In view of the fact that large numbers of electric tools have hitherto come from Germany, the list should prove particularly interesting at the present moment.

**SMALL GENERATING SETS.**—"Panda" electric generating sets are fully described in a pamphlet received from Messrs. Pooley & Austin (25 Victoria Street, S.W.). They have been developed to meet the demand for a dependable and efficient set suitable for yacht, bungalow, and small country house lighting, and they are of British manufacture. The set consists of a Mawdeley dynamo driven by a single-cylinder two-stroke engine running on paraffin or petrol.

**N.P. PUMP RINGS.**—A leaflet just to hand describes the one-ring design of the "N.P." Patent Pump Bucket, a large number of which are now being used successfully in the boiler feed pumps of the North Staffordshire Railway locomotives. The packing ring is of special composition, which is unaffected by any boiler feed temperatures, and which, owing to its adaptability, can be used in a worn liner where an ordinary cup ring packing would be unsatisfactory. Owing to the construction of the bucket, the pressure of the ring against the inside of the liner is automatically adjusted to suit the head against which the pump is working. The makers are the N.P. Pump Bucket Co. (11 Queen Victoria Street, E.C.), and mention may be made of the fact that these pump buckets are, and have always been, British made.

**Australian Import Trade in 1913.**—From a return made by H.M. Trade Commissioner in Australia, it appears that the total imports of "competitive merchandise" from the United Kingdom in 1913 amounted to £38,265,340, as against £6,886,441 from Germany. The proportion of British goods was slightly higher than in 1912. The increased proportion of British imports of machinery, metals, and metal manufactures is particularly high. Details as to the imports of the various classes of goods into the several States of the Commonwealth, showing the shares taken by the United Kingdom, Germany, and the United States, have been specially compiled by the courtesy of the Commonwealth Statistician's Department at the request of H.M. Trade Commissioner, and upon application from British firms H.M. Trade Commissioner, whose address is Commerce House, Flinders Street, Melbourne, will be glad to furnish detailed figures regarding any particular class of goods. Meanwhile a statement showing the imports into the Commonwealth under main headings, as well as the imports from the United Kingdom, Germany, and the United States, also the United Kingdom's share of the imports under these headings into the several States, may be seen on application to the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, E.C.

### CORRESPONDENCE

#### ARC LAMP GLOBES.

To the Editor of "ELECTRICAL ENGINEERING."

SIR,—I enclose you drawings of the different arc-lamp globes used in this borough, and I shall esteem it a favour

if you will insert same in your paper, so that other corporations and municipalities of the British Isles who use similar globes can get into communication with myself with a view to arriving at the approximate quantity used per annum. This information would greatly assist British firms in a position

to manufacture, who will no doubt get into touch with us on seeing this article.—Yours faithfully,

57 Pratt Street, Camden Town, SYDNEY W. BAYNES,  
London, N.W. Chief Electrical Engineer,  
September 11th, 1914. St. Pancras Borough Council.

### THE OSRAM LAMP WORKS.

To the Editor of "ELECTRICAL ENGINEERING."

SIR,—In view of the statements that have been made in the papers and elsewhere as to the presence of German capital in the Osram Lamp Works, Ltd., which, appearing by themselves, give a totally erroneous view of the real position of affairs, we beg to state the following:—

The Osram Lamp Works, Ltd., situated at Hammersmith, were formed as an adjunct of the General Electric Company, Ltd., a concern which, with its subsidiary undertakings, possesses nearly £2,000,000 capital, subscribed by 5,000 British

shareholders. The factories of the General Electric Company, Ltd., are in this country exclusively, and employ some 10,000 British workpeople. The Osram Lamp Works, Ltd., do not trade, but manufacture lamps exclusively for the General Electric Company, Ltd.

We desire to explain how this industry was established in England. The metal filament lamp is essentially an Austro-German invention, and when the General Electric Company, Ltd., first realised its importance they immediately endeavoured to promote the manufacture in this country. The difficulty was, however, that the Continental patentees contemplated supplying the English market from Continental works. The General Electric Company, Ltd., offered to find the money for a manufacturing Company through the Robertson Lamp Company, Ltd. (one of its subsidiary Companies), but owing to the differences of opinion that then existed as to the merits of metal filament lamps, a fixed price for the purchase of the patents could not be agreed upon, and the patent owners not unreasonably demanded, and were granted, shares in the factory as payment for their patents and experience.

The passing of Mr. Lloyd George's Patent Act, with its avowed object of introducing industries to this country, materially assisted in the concluding of these negotiations.

If this policy had not been adopted by the General Electric Company, Ltd., there would have been no Osram Lamp Works in England to-day. Thus the General Electric Company, Ltd., forced the establishment of the Hammersmith factory, which eventually involved an outlay in buildings and equipment (in which British workpeople benefited) of over £100,000, and which provides constant employment for approximately 1,500 British workpeople in addition to the very large staff employed by the General Electric Company, Ltd., in the sale and distribution of Osram Lamps.

Yours faithfully, for and on behalf of

The General Electric Company, Ltd.,

67 Queen Victoria Street, E.C. JAMES Y. FLETCHER,  
Sept. 27th, 1914. Manager, Osram Lamp Department.

## THE BRITISH THOMSON-HOUSTON CO.

To the Editor of "ELECTRICAL ENGINEERING."

SIR,—I notice in some of the electrical papers various letters which inquire into the composition of the British Thomson-Houston Co., Ltd.

Although the files at Somerset House tell the whole story, few take the trouble to make an examination, and therefore the following may be of interest, and I would appreciate it if you will publish the information in full.

Our capital consists of 80,000 shares of the par value of £10 each and £186,215 of debentures

Our shares are held as follows:—

44 English shareholders holding	10,458	shares
11 French " "	3,109	"
1 Belgian " "	83	"
9 American " "	64,876	"
1 German shareholder resident in Cologne	333	"
1 German shareholder resident in England	1,141	"
Total	80,000	"

Neither of these last two shareholders, so far as we know, are in any way connected with electrical manufacturing companies either here or in Germany.

We have 106 debenture holders, all of them resident in England, and all English, with the exception of one French lady, who holds £2,000 par value, and she resides in Folkestone.

We have not a single German in our employ, or in any way connected with the Company.

Our active Board consists of the following:—J. F. NAUHEIM, who represents the shares held by Lord Rothschild in our Company. He has resided here most of his life, and has been naturalised between thirty and forty years; GEORGE FRANKLIN, of Sheffield and London, who was at one time Lord Mayor of Sheffield, and who was chairman of the National Telephone Co.; OWEN H. SMITH, who came on originally to represent our debenture holders. He is one of the partners of "The Proprietors of Hay's Wharf, Ltd.," F. FRASER, a Scotsman, who is also our Secretary; W. C. LUSK, Manager of our Commercial Departments; H. N. SPORBORG, our Chief Engineer; and myself, the Managing Director. We (the latter three) are American born, and have been here from ten to twelve years.

The other members of our Board are three Americans residing in New York, who represent large shareholders, and one of them for many years resided in London, namely:—C. A. COFFIN, E. W. RICE, JUN., E. A. CAROLAN. The two former are Chairman and President respectively of the General Electric Company of New York, the parents of this Company and its predecessor, the Thomson-Houston Co., forming the original basis of our Company. C. BURRELL, an Englishman, who has spent most of his life in France, now living in Paris; E. THURNATER, who is

an American citizen, also living in France. These two are Managers of the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston, and represent on our Board the French shareholders.

The total number of our employees is about 5,600, a large number of whom are, of course, young women in the lamp factory.

Our factories are at Rugby, Coventry, and Willesden.

So far about 900 of our employees have joined the colours, which is over 50 per cent. of those who are eligible, and all who have joined, both married and single, receive half wages or salaries while they are away, and their places will be kept open for them until their return to the fullest possible extent. I might also add that no changes have been made in the salaries of those who remain in the Company's employ.

Faithfully yours,

H. C. LEVIS,

Managing Director.

London, Sept. 14th, 1914.

**Record Electrical Co.**—The Record Electrical Co., Ltd., write us as follows:—"We have been informed that a statement has been circulated to the effect that the Record Electrical Co., Ltd., is financed by capital of an alien enemy. The directors wish to give notice that, as this statement is entirely false, they will take immediate action in the courts against any person who, to their knowledge, is party to the circulation of such libellous report."

**Wm. Geipel & Co.**—We have received a letter from this firm to contradict certain rumours which have been circulated to the effect that the firm is alien. Mr. Geipel himself and his entire staff are English born and bred. The firm's manufacturing department, we are informed, has recently extended its London works, which is now equipped for employment of 200 hands.

**Siemens Bros. Dynamo Works and the War.**—Up to last week 400 men had left Siemens Bros. Dynamo Works at Stafford as Reservists or as members of the Territorials or the new army, and a further 120 men have joined from the company's various branches. Ample provision is being made for dependents according to the particular circumstances of each case, and all men will be re-engaged in the same positions at the close of the war.

**The Hart Accumulator Co. and the War.**—Some 40 employees of the Hart Accumulator Co. have joined the forces, and in order to relieve any distress in the families of these men, the whole of the company's employees are contributors two hours' pay each week. In this way, grants to each family, ranging from 15s. per week downwards, will be made, depending on the circumstances. These subscriptions are entirely voluntary, and are being augmented by personal weekly contributions from the directors, and by a weekly grant from the company. The company undertakes to provide the men with their old employment on their return home.

**Dispute as to Ownership of Carbons.**—With reference to the note on p. 489 of our issue for September 3rd, no evidence was offered when the three men concerned appeared at the Central Criminal Court on Friday on the charge of breaking into the Foster Engineering Co.'s works. The civil action will proceed, but the Common Serjeant said it was not a matter for the Criminal Court.

**Damaging Signals on L.B. & S.C. Railway.**—A foreman in the employ of the London Brighton & South Coast Railway Co. has been sentenced to twelve months' hard labour for damaging electric signal wires on the line at Battersea. It was stated that the offence was committed while soldiers were being conveyed south, and it seems to have been done because the offender was not allowed to work overtime.

**The Institution of Electrical Engineers and the War.**—Mr. W. Duddell, President of the Institution of Electrical Engineers, has addressed a letter to members pointing out that the Institutions of Civil, Electrical, and Mechanical Engineers have been invited by the Lords Commissioners of the Admiralty to assist in obtaining picked men for the Divisional Engineer Units and Signal Company of the recently formed Royal Naval Division. The units to be raised are one Divisional Headquarters R.E., two Field Companies R.E., and one Signal Company. A camp is under preparation near Martin Mill Station, Kent, and the total authorised strength is 500, with eighteen officers, in addition to the Commanding Royal Engineer and a medical officer. The terms of enlistment will be for the war, but not in any case exceeding three years. A special recruiting office has been opened at 2 Savoy Hill, Victoria Embankment, London. Many members of the three Institutions having previously expressed a desire to serve in the Army, the formation of an Engineering Societies' Battalion had been contemplated.

### A B.T.-H. MOTOR CAR MAGNETO

IN our issue of August 20th, p. 462, we referred to an important meeting of British motor-car manufacturers for the purpose of making arrangements for the supply of magnetos for motor-cars and motor-cycles. The greatest development in the motor-car industry is to be traced to the substitution of the magneto for the accumulator for firing the charge in the cylinders. For some unexplained reason, the manufacture of this essential piece of apparatus has been left mainly in the hands of German firms, and it has often been a subject of comment that the large British electrical manufacturers have not taken the matter up. The British Thomson-Houston Co., of Rugby, however, has been experimenting with such a magneto for the past twelve months, and the present moment, therefore, is particularly opportune for placing it upon the

FIG. 1.

market. This magneto, which is manufactured at the Company's Coventry works (a description of which appeared in *ELECTRICAL ENGINEERING* of June 25th, p. 361) has demonstrated its ability to stand up triumphantly under the severest service conditions. In designing and building it, the Company has brought its vast electrical experience to bear upon the subject, and has followed, with the greatest care, the accepted line of magneto manufacture and practice, so that the B.T.-H. magneto is interchangeable with the standard make of magneto, and will give equally satisfactory, if not superior, results.

Like most modern magnetos, it has a base and end plates of aluminium, and is totally enclosed and weatherproof. There is a fine gauze protection cover over a small opening in the top, which enables air to reach the armature so as to dissipate any vapours which may be formed. The magnets, which are made of a special grade of tungsten steel possessing great retentivity, are longer than is usually the case, this resulting in a

FIG. 2.

more permanent magnet, and a hotter spark at low speeds. The armature is neat and compact; the condenser is contained in a brass cap at one end of the core, and its dielectric consists solely of pure mica sheets. Here, as in many other directions, in the manufacture of this apparatus the electrical experience of the B.T.-H. Company has been of valuable assistance. The high voltage winding is covered with a heavy jacket of suitable insulating material, which by subsequent treatment is converted into a homogeneous waterproof unit. As an additional safeguard for the armature insulation a safety spark-gap is provided, which, in the event of the voltage rising to an abnormal value, acts as a safety valve to prevent breakdown of the insulation. The contact-breaker is seen in Fig. 1,

and, of course, is easily accessible and detachable. The contact points have been given special attention, and they will be found very substantial and ensuring long life. Fig. 2 gives a good view of the rotating and stationary portions of the distributor. The whole is made absolutely waterproof.

These magnetos are at present available in three sizes, a small size suitable for single cylinder motor cycles, and two larger sizes intended for use on four-cylinder cars; other sizes are in course of development.

### A MAZDA SHOWCARD

OUR black-and-white reproduction of the new Mazda showcard being issued by the British Thomson-Houston Co.,

Ltd. (London and Rugby), conveys but a poor impression of the rich colouring and general effect of the original. Dealers should find it effective in stimulating sales.

### "SIMPLEX" HAND LAMPS

TWO electric hand-lamps designed to comply with Home Office Regulation 13 have been produced by Simplex Conduits, Ltd. (Garrison Lane, Birmingham). Both lamps are built on similar lines, but in the case of Fig. 2 a more substantial enamelled iron guard is fitted. The general

FIG. 1.

FIG. 2.

construction of the lamps is that neither the iron guard nor the brass clamping ring can become charged, and as both the lamp-holder and lamp-cap are surrounded by a protecting sheath of insulating material there is no necessity for earthing. A leather loop is attached to the handle.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Ashton-under-Lyne.**—Sanction has been given to the borrowing of £42,015.

**Bolton.**—The Local Government Board has sanctioned the borrowing of £1,463 for the electricity undertaking.

**Bristol.**—A loan of £42,000 is to be taken up for mains, sub-stations, and services.

**Cleckheaton.**—A Local Government Board inquiry was held last week concerning a loan of £2,200 for electrical extensions.

**Heywood.**—The Electrical Engineer has prepared plans and estimates for the proposed bulk supply from Bury.

**Sheffield.**—Mains are to be carried to the Lodge Moor Hospital at an estimated cost of £5,080. Several other mains extensions are to be carried out.

**Torquay.**—A Local Government Board inquiry was held last week concerning a loan of £16,000 for the general purposes of the electricity undertaking, and £500 for the electric lighting of Princess Gardens. Mr. C. W. Salt, the Borough Electrical Engineer, told the inspector that new plant is required immediately.

**Walsall.**—Extra high-tension switchgear; static transformers; low-tension switchgear. Consulting Engineer, E. M. Lacey, 12 Victoria Street, London, S.W. Tenders to Town Clerk by September 29th.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Chelmsford.**—Additions to hospital.

**Colchester.**—Extensions at Infectious Diseases Hospital.

**Eccles.**—School, Anson Street. Architect, J. Knight, 5 Cross Street, Manchester.

**London.**—New wing and alterations to London Institution, Finsbury Circus. Architect, Professor F. M. Simpson, 88 Gower Street, W.C.

**Middlesbrough.**—School at Grove Hill.

**Scarborough.**—Electric lighting of the workhouse (£5,950).

**Stoke-on-Trent.**—School. Director of Education, Town Hall, Hanley.

**Tyldesley.**—New town hall.

**Warrington.**—School, Parr Street.

### Miscellaneous

**Brighton.**—A supply of electrical fittings is required by the Brighton Guardians. Clerk. September 22nd.

**India.**—The Great Indian Peninsula Railway Co. requires supplies of lamps and fittings. Secretary, 48 Copthall Avenue, E.C.

**Warrington.**—The Guardians require a six months' supply of electrical goods. (German and Austrian goods barred.)

**Whitefield.**—Electric motors are required for the sewage disposal works. Borough Engineer.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Manchester.**—A contract for a two years' supply of C.C. and A.C. meters has been placed with Ferranti, Ltd.

**Sunderland.**—The following firms quoted for the two 1,500-kw. A.C.-D.C. converters, for which tenders were recently asked:—General Electric Co. (accepted); British Westinghouse Co.; British Thomson-Houston Co.; Bruce, Peebles & Co.; Dick, Kerr & Co.; Electric Construction Co.; Mather & Platt; Siemens Bros. Dynamo Works; Vickers, Ltd.

**Sydney.**—A contract has been placed with Willans & Robinson for a 5,000-kw. turbo-alternator with condensing plant. The plant consists of a standard Willans disc and drum turbine, to be coupled to a Dick, Kerr alternator, the turbine exhausting into a Willans surface-condensing plant with rotary air pumps. This plant is to take the place of a

German plant ordered some time ago. The municipality has also given the contractors exceptionally favourable terms of payment, which embody monthly instalments as the work proceeds, up to a total of 80 per cent. of the value of the contract on shipment. It speaks well for the reputation of the firm that these terms have been granted, and great credit is due to the Corporation for encouraging a home firm in this way. Messrs. Preece, Cardew & Snell have acted in this country for the Corporation, and it is probable that they have played a not inconsiderable part in the settlement of the terms of payment.

**York.**—The tender of the British Westinghouse Co. has been accepted at £542 10s. for transformers.

**Price of Copper.**—Although the Metal Exchange is not open for business in the ordinary course, the following may be taken as the official quotation for electrolytic copper bars, viz., £55 10s. to £56. (Last week, £59 to £60.)

## APPOINTMENTS AND PERSONAL NOTES

Mr. P. A. Lange, Managing Director of the British Westinghouse Co., has adopted the name of Lang. Mr. Lang is a naturalised British subject, and was formerly an American citizen.

The following vacancies have occurred in the Newport (Mon.) Electricity and Tramways Department:—Senior Engineer-in-Charge, £104 per annum; Junior Engineer-in-Charge, 30s. per week; Switchboard Attendant, 25s. per week; Mains Foreman, £2 10s. per week. Applications to Borough Electrical Engineer. (See advertisement on another page.)

A teacher of engineering subjects is required by the Kent Education Committee for the Dartford Technical Institute. (See an advertisement on another page.)

A shift engineer is required temporarily at Tunbridge Wells to fill a war vacancy. Borough Electrical Engineer.

## LOCAL NOTES

**Dover: Bulk Supply.**—The offer of the South-East Kent Electric Power Co. to give the Corporation a supply in bulk came up again at the last meeting of the Council. It was decided, however, to reply that it is not deemed advisable to incur the necessary capital expenditure, having regard to the fact that the price quoted of 3d. per unit for one million units, with a reduction according to the quantity down to 0.72d. per unit, would not involve much economy in consequence of capital charges.

**Hamilton: Valuation of Electricity Works.**—The valuation of £1,288 placed upon the electricity works of Edmundson's Electricity Corporation was appealed against last week, and a reduction claimed to £1,110. The question in dispute was whether superheaters and chain-grate stokers were to be regarded as tenant's or landlord's improvements. The assessor looked upon them as landlord's improvements, adding to the value of the works and profit-making capacity. The Works Manager, however, took a contrary view, and the Court by a majority agreed to reduce the valuation to the figure asked for.

**Rochester: Street Lighting.**—The contract with the Rochester Gas Co. for street lighting has been terminated, and an agreement entered into with the Kent Electric Power Co. for the electric lighting of the High Street and North Street.

**Southampton: The Report on the Electricity Undertaking.**—The joint report by Sir John Snell and Mr. Ernest Edmonds, dealing with the general position of the electricity undertaking and the policy hitherto pursued in connection with it (ELECTRICAL ENGINEERING, August 6th, p. 452) is to be brought before a special meeting of the Council. This decision is the result of an amendment to the original proposal that the report should be referred to the Parliamentary Committee, who should in turn report to the Council.

### SUMMARY

A DETAILED description of the manufacture of Osram lamps, as at present carried out at Hammersmith, appears on pages 512 and 513.

THE B.E.A.M.A. have removed their ban on firms in which the controlling interest is held in Germany and Austria if these firms manufacture largely in this country.—A letter from representative Siemens workmen protests against "malicious attacks" on the firm from various sources. (Page 514.)

WE describe the Ediswan works, and publish some interesting illustrations taken in the works. (Page 515.)

THE Electrical Vehicle Committee have sent us details of the charging plug they have standardised, and we give full particulars of this, together with drawings and dimensions, and a photograph of a plug actually made already by one manufacturer to this standard. (Page 516.)

THE Board of Trade Report upon accidents on railways in the United Kingdom during 1913, recommends a more extensive use of electric track signalling and also the adoption of some form of cab signalling or wireless control to avoid mistakes by drivers. The electric lighting of railway carriages is also referred to. (Page 517.)

THE Board of Trade Intelligence Department has received many applications from persons abroad desiring to purchase British electrical goods now that German exports have ceased. (Page 517.)

THE running of rotary converters in parallel is discussed in our Questions and Answers columns. (Page 518.)

AMONG specifications published last week at the Patent Office is one relating to the use of phosphorus pentoxide for preventing lamp bulbs blackening, and one for a double armature traction motor. Other subjects include arc lamp carbon holders to economise carbon ends, cooking apparatus, and telephony. An important patent relating to the Wright electrolytic meter expires this week. (Page 519.)

INFORMATION just come to hand, *via* Switzerland, states that already at the end of last month, the Allgemeine Elektrizitäts Gesellschaft found it practically impossible to make any deliveries, export was quite interrupted, and the electrical department was working on very short time. Existing prices were withdrawn, and in many cases were increased by 10 and 20 per cent. Other German firms have been similarly affected. (Page 519.)

THE Edinburgh Corporation proposes, contrary to its usual practice, to contribute a large sum to relief of rates.—A proposed loan of £23,000 at Walsall is to be postponed in the hope that the money will be raised cheaper later on.—Some comments upon purchasing arc lamp carbons abroad were made at a recent meeting of the Bristol Corporation.—A new power station is recommended at Belfast. (Page 520.)

SHORT articles on some electric light fittings, a new winch and electric heaters, a photograph taken at the opening of the Ediswan rifle range, and a letter criticising a circular issued with regard to electric lamps, appear on p. 521.

A 3,000-kw. turbo-alternator is to be purchased at Woolwich; sub-station equipment is required at Littleborough; a water-tube boiler at Lowestoft, and rotary converters at Hornsey.—A loan of £8,000 is to be taken up at Bispham, and electric lighting schemes are under consideration at Troon and Kelso.—Electrical fittings are required at West Ham, and tramway extensions are contemplated at Leicester and York. (Page 522.)

**Engineer Units, Royal Naval Division.**—A Joint Committee of the Institutions of Civil, Electrical, and Mechanical Engineers is engaged in the selection of men for the Engineer Units of the Royal Naval Division. There are still some vacancies to be filled, and applications are invited from engineers and architects who are members of professional societies. Application to be made in person at the Special Recruiting Office, at No. 2 Savoy Hill, W.C., between 10 a.m. and 1 p.m., or between 2 p.m. and 4 p.m.

**The London Electric Supply Scheme.**—The London County Council is proposing to hold a conference on October 2nd with the Borough Councils, who are authorised distributors of electricity, in order to ascertain their views before submitting definite and detailed proposals with regard to the future of the supply of electricity in London.

### THE OSRAM LAMP WORKS

THE Osram lamp works have been thrown open to the public. Large advertisements have appeared in the daily papers inviting all who might care to do so (with the exception of competitors) to apply for an invitation to inspect the factory, and to convince themselves that Osram lamps are made there in enormous quantities. Although we did not need convincing on this point, we gladly accepted a special invitation extended to us by Mr. C. Wilson, the General Manager, and spent an interesting two hours at the works. Mr. F. P. Driver, the Works Manager, who took our representative round, showed him every detail of manufacture with the utmost frankness, in-

The first process is the reduction of the tungsten from the ore, which is now being carried out at the lamp works. It results in a supply of tungsten in a finely-powdered state, and we saw the powder worked up into a form sufficiently tough and ductile to be drawn into a fine wire. It is first compressed under great hydraulic pressure into the shape of a thin, rectangular bar, which is maintained at a high temperature in a hydrogen flame in order to remove all impurities. A current of electricity is then passed through it, bringing it into a more solid state, and preparing it for the process of "swaging," that is to say, a process of hammering under heat, which alters the shape of the ingot to a long, thin rod of ductile tungsten. This rod is then

FIG. 1.—PART OF THE WIRE-DRAWING SHOP.

FIG. 3.—FILAMENT MOUNTING.

FIG. 2.—MAKING THE GLASS STEMS AND FEET.

FIG. 4.—TUBULATING.

cluding even the manufacture and drawing of the tungsten and some new automatic machines, which have recently been introduced, for making and assembling the parts of the lamps. Some of the latter are fully automatic; if the blowpipes for heating the glass were not visible one might have thought that brass or iron was being worked, for in some of the machines there is marked resemblance to the complex and accurate actions of the familiar automatic machines used in the lighter engineering works.

The works are at Brook Green, Hammersmith, and occupy a large six-storey building. Every part of the lamp is made at the works, with the exception of the bulbs, which are made at an affiliated works at Lemington-on-Tyne (described in our issue of September 10th), and the lamp caps, some of which are already being supplied from the General Electric Co.'s Birmingham works.

drawn down to the required fineness, step by step, more or less in the usual way. The tungsten wire is wound upon bobbins, and stored for use in the factory as required.

The glass and metal support for the filament is made up of the glass foot (through which the leading-in wires pass) welded to the glass rod or stem, which has a spider of metal wires at each end. The foot, a short glass tube with a funnel-shaped end, is made by full-automatic machines. The tubes are cut into the lengths required for the foot by a machine which combines a blow-pipe and automatic glass cutting action. The short lengths of tube are then placed into hoppers, and fed into an automatic machine, which puts a flange on one end of each tube; a blow-pipe softens the end of the tube, which is then automatically flared out into a funnel-shaped flange by a special tool. One girl tends 26 of these machines. The stems are cut

and shaped in another machine. A long length of glass rod is fed into this machine, the two studs for carrying the supports of the filaments are formed by heating the two points by a blow-pipe flame, and exerting pressure on the rod, and the stem is then cut off with these two studs at the ends. The next step is the bringing

FIG. 5.—EXHAUSTING.

together of the foot, the stem, and the leading-in wires. These are placed together, the unflanged end of the tube is brought under a blow-pipe, and at the right moment clamped flat over the leading-in wires. The leading-in wires are made up of a length of copper wire to connect in the lamp cap, a very short length of platinum to pass through the glass, and a piece of nickel wire for the part within the bulb to make contact with the filament.

The spider of wires which support the filament at the upper or cap end of the lamp are of nickel, and are out and formed with the necessary loop by an automatic machine, and they are heated and inserted into the upper stud of the stem by hand. It is wonderful to see how accurately these are inserted at even distances apart by the work-girls. To some extent, also, the finer wires for the supports at the lower end of the stem, which are of fine flexible molybdenum wire, are also inserted by hand, but an ingenious machine recently introduced has been devised which cuts and inserts a set of these spring supports at one operation.

FIG. 6.—CAPPING.

The spring supports are inserted without any loops, and these are made at the next step in the process, when the angles of the spider are also automatically adjusted.

The spider is then ready for the winding on of the

filament, which is done by hand on a special machine and with an ingenious winding pliers. The bobbin of tungsten wire is fixed on to this light hand-tool, and the wire wound up and down over the supports rapidly and neatly. The end of the wire is first clamped on to the end of the leading-in wire, and is then wound over independent supports, clamped to the other leading-in wire, and cut off. The spring supports themselves are not strong enough to stand the operation of winding. A bell-glass is then dropped over the filament, and current is passed through the wire in an atmosphere of hydrogen; the artificial supports are then withdrawn, and the spring supports hold the filament at the requisite tension. A row of operators at this work is seen in Fig. 3.

The "cage," i.e., the completed foot, stem, and filament, is then ready to be fixed into the lamp bulb. The bulb is first pierced by a blow-pipe flame, and the exhausting tube is welded on to it. The rough flange at the other end of the tubulated bulb is then neatly cut away by a rotary blow-pipe action. The cage is inserted upwards into the bulb, which rests in the machine with the exhausting stem upwards. The lower part of the bulb is then held in the blow-pipe and welded to the flange of the glass foot. This "sealing in" and the next operation of exhausting is allotted to the most skilful of the workers.

The exhausting affords a very good example of the ingenious combination of machinery and hand-labour. The bulbs are exhausted, six or eight at a time, and the operators, who sit on trolleys running on the rails of a small tramway, are enabled to pass rapidly up and down and supervise several sets of lamps simultaneously. After exhaustion the bulbs are sealed off, and pass into the testing department.

The final process is the placing on of the cap and the soldering of the leading-in wires. The General Electric Company, as has been mentioned, is now starting to make its own caps, and it has for some time made the cement by which the cap is fixed to the lamp. The machine which places the requisite amount of cement inside the ring of the cap was specially designed in the Osram works, and represents a very ingenious solution of a problem which is superficially easy, but, as a matter of fact, is very difficult. The caps are fixed on the lamps under heat, which is supplied by an electric heater fitting round the cap. The leading-in wires are then cut off and soldered, thus completing the lamp. A short final test is made of the lamp, which is branded and cleaned before being packed. It should be mentioned that at every step in the process the product of each department is carefully inspected before it is accepted by the next department. In this way the highest standard of work is maintained throughout the whole process of manufacture.

We need refer to the packing and despatching department only to say that the freedom with which the packers are able to handle lamps, and the express rate at which lamps are rolled up in their cartons by piece-work hands, is sufficient to show that the days of fragility of tungsten lamps are over.

Our readers will have gathered some idea as to the magnitude of the works from the description we have given of the main processes involved in the manufacture of Osram lamps and the large number for which it has been found economical to employ automatic machines. With the additions which were completed last spring, the works will be capable of dealing with an output of between 12,000,000 and 14,000,000 lamps per annum.

This article would not be complete without mentioning half-watt lamps. The installation of plant for the manufacture of these had just been completed and put into operation when the war broke out. We are informed that owing to the dislocation of labour caused by a large percentage of the staff and employees

enlisting, it was found necessary to concentrate all the available hands upon the production of the ordinary types of tungsten lamp, and the manufacture of half-watt lamps could not be begun immediately. It is confidently expected that this department will be in full swing within a month or two.

### THE B.E.A.M.A. AND THE WAR

ON September 4th the Council of the British Electrical and Allied Manufacturers' Association passed the following resolutions:—

1.—Resolved that, having regard to the state of war, it is the opinion of this Council that trading with—

(1) Any company incorporated in Great Britain the controlling interest in the share capital of which is held by Germans or Austrians,

(2) Any German or Austrian firm, or branch or agency of a German or Austrian firm, trading here, whether in the same or another name, is against the best interests of the British electrical and allied industries.

2. Resolved that the Secretary be and he is hereby instructed to invite members of the Association who fall under Definitions (1) or (2) in the first resolution to resign their membership.

3.—Resolved that members of the Association be instructed that, in the opinion of this Council, it is against national interests for them to buy from or sell to firms falling under Definitions (1) or (2) in the first resolution.

Copies of these resolutions were sent to Members and Associates of the Association; and Members, that is to say manufacturers in this country, were asked to state by September 9th whether they "assented to" these resolutions. This appears to be the usual practice of the B.E.A.M.A., and we understand that such resolutions are not considered effective unless there is a majority of members in favour of them. We duly received information of this action of the Council and had copies of the resolutions before us, and on September 9th, at the last moment before going to press with our issue of September 10th, we communicated with the Secretary of the B.E.A.M.A. We were told that the voting would not be considered by the Council for several days; and we were asked not to publish the resolutions in the meantime. Although we naturally complied with this reasonable request, we regret to say that our contemporaries, the *Electrical Review* and the *Electrical Times*, to whom a similar request had been made by the Secretary, published the resolutions nevertheless. This is the more regrettable as the resolutions have now not been confirmed, and in the circumstances no good object could have been served in making them public, and extending a somewhat bitter controversy outside the circle of the Association itself.

We have reason to know that the B.E.A.M.A. had been in constant communication with the Board of Trade as to the interpretation to be placed upon the first proclamation by the Government as to trading with the enemy, and, as no definite pronouncement could be obtained from them, the above resolutions were passed after Counsel's opinion had been taken. Although we understand that a large proportion of the membership were in favour of the steps indicated in them, there was considerable expression of opinion against any such action being taken against firms with works in this country. The Board of Trade were also informed of the B.E.A.M.A. Council's recommendations, and we have reason to believe that a broad hint was given that the Board would not approve of any combined boycott of firms manufacturing in this country with German capital. This is hardly to be wondered at, for two reasons. There would be great distress if large works had suddenly to close and a large number of workpeople were thrown out of employment almost without warning; and some of the works in question are at present engaged in executing Government contracts.

On Friday, September 11th, the B.E.A.M.A. issued a state-

ment that in view of the Government Proclamation dated September 9th (published in our last issue), and of "representations" made to them—representations which we need hardly suggest have emanated from a far higher authority than that of our two contemporaries already alluded to—they felt justified in modifying their previous resolutions, in favour of companies which largely manufacture here, as distinct from those which are merely branches (whether incorporated in Great Britain or not) of concerns domiciled in an enemy country. This distinction, the statement adds, "gives effect to the dominant feeling of members."

The Council of the Association certainly made a *faux pas* in passing resolutions or in making definite recommendations in so serious a matter, upon what they evidently regarded as a highly controversial question and upon which they desired to have a vote from their members before deciding on a definite policy. Bitter feeling has been aroused and the B.E.A.M.A. is divided into two camps, and nevertheless the position is practically "as you were," with one exception. This exception, however, is an acceptable one, namely, that firms in which the controlling interest is held in Germany or Austria must cease their connection with the Association and its members *unless they manufacture largely in this country*. The result might, however, have been brought about without all this pother.

It is to be regretted that the B.E.A.M.A. could not go further and put the whole thing on a sensible and logical basis by issuing a list of the firms barred. Apparently they do not consider this comes within their province, or they are afraid of legal consequences if they issued a "black list."

We have received for publication a long letter from Stafford, signed by twelve workmen employed by Messrs. Siemens Bros. Dynamo Works, all members of trade societies. We publish it below in slightly abbreviated form.

We, being representatives of organised workers employed by Messrs. Siemens Bros. Dynamo Works, Ltd., Stafford, desire to call public attention to a few facts concerning this company, which has lately been subject to malicious attacks from various sources, the same tending to damage the future trade of this old-established firm, founded about the year 1847 A.D. by Sir William Siemens, who was the pioneer of a new industry, which has since reached large dimensions.

At the outbreak of the present hostilities, many of our fellow British workers were called up for service, and the dependants of these men are being supported by the firm in such a manner that the fear of want has been dispelled; in many cases this help amounts to full wages allowance.

The works have been kept on full time up to the present in spite of many difficulties, and the management are doing their utmost to continue these acceptable conditions. Great encouragement has been given to the young men to enlist in the new army, and some hundreds have responded. All men who are serving are having their situations kept open for them. The feelings of these men could be better imagined than described if, on their return, after enduring the privations of warfare, they found the gate of their old firm closed.

In normal times about 2,000 workpeople are employed at these Stafford works, out of which are approximately 4 per cent. foreigners, comprising Germans who have grown grey in the service of the firm, others born in England, and a good number of other nationalities not alien enemies.

It has also been stated in reference to Siemens that Germany benefits to the extent of £35,000 annually in profits without any corresponding advantage to this country; seeing that the company pay quite £100,000 per annum in wages at their Stafford works alone, is not this a decided counter availing advantage?

We would urge all Corporations and other public bodies to consider these facts before letting prejudice interfere with the welfare of the British workers.

**Electro-Harmonic Society.**—The usual programme of smoking concerts and ladies' nights has been arranged for 1914-15. The first smoking concert is on Friday, October 9th, and the ladies' night on Monday, November 16th.

**Birmingham & District Electric Club.**—The next monthly meeting will be held at the Swan Hotel, New Street, Birmingham, on Saturday next, at 7 p.m., when a discussion will take place on "The Effect of the War on the Electrical Trade."

## THE EDISWAN WORKS

THROUGH the courtesy of Mr. C. E. Hunter and Mr. E. Gimmingham, the Managing Directors, we have been afforded an opportunity of visiting the

various works in the United Kingdom, these are the only ones in which every part of the manufacture is carried out, including not merely the assembly of the lamps, but also the blowing of the bulbs, the preparation of the tungsten and drawing the filament, and making the lamp caps. About 2,500 hands are employed there—about 1,400 in the manufacture of

FIG. 1.—WINDING THE FILAMENT.

FIG. 3.—EXHAUSTING RADIATOR LAMPS.

FIG. 6.—ONE OF THE ACCESSORY ASSEMBLING SHOPS.

works of the Edison and Swan United Electric Light Co. at Ponder's End, and of viewing the whole process of manufacturing metal filament lamps there. Of the

lamps and the remainder in the departments devoted to fittings, accessories, &c. Every department seemed as busy as it could be. We first inspected the labora-

tory, and we were interested to learn that tungsten can be prepared from a tungsten concentrate obtainable in Cornwall, so that it is possible to be absolutely independent even of imported raw material for lamp manufacture. Molybdenum, used for one of the two spiders of flexible wires supporting the filament, is also made at the works, and although these two metals—owing to the fineness of the wires required—are only used in comparatively small quantities, so that it may

FIG. 7.—FOUNDRY.

not always be worth while to make them there, the great point is that, by being able to do so, the works can be quite independent of outside assistance.

The glass-blowing was referred to, and the glass-houses illustrated, in our issue of August 27th. It is remarkable how simple this skilled operation appears. The molten glass is collected at the end of a long rod, and blown by the mouth until the bulb commences to form. This is then placed in an iron mould previously wetted with water, and the bulb blown to shape. The cushion of steam between the glass and the mould prevents actual contact with the iron. The bulb is then removed from the rod, and the operation is repeated; it takes only a few seconds. To keep pace with the increasing demand for lamps, an additional glass-house is being erected, and will shortly be in use.

Some of our illustrations show other processes in the course of manufacture. The operator in Fig. 1 is winding the filament on the supporting hooks after the foot and the stem with the leading-in wires and sup-

into the bulb, and Fig. 4 illustrates the next process, that of exhausting the bulb. Fig. 5 gives an idea of the large number of workgirls employed at each of the various operations; it is part of one of the main assembling shops.

We have only space to refer briefly to the other departments of the Ediswan works. Large quantities of carbon filament lamps are being made, including radiator lamps. Two of the exhausting benches for the latter are shown in Fig. 8. Several shops are devoted to special lamps, both carbon and metal filament, for the Edison Swan Company has always paid particular attention to these. Fig. 6 is a view of one of the shops devoted to the assembly of accessories—switches, ceiling roses, fuses, &c.—and Fig. 7 is one end of the foundry. The company does all its own casting, both brass and iron. In the machine shops it possesses some of the very finest automatic machines, both for light brass work and for miscellaneous steel parts. As already mentioned, lamp caps are now being made at the works, and a special series of automatic machines has been evolved for this purpose. Besides the parts required for the company's own manufactures, a variety of work is done for other firms, and a wide range is covered; in one shop we saw coffee machines being made; in another, parts for aeroplanes.

To conclude, in one brief sentence, the Ediswan works is at the same time the oldest and one of the most modern and complete lamp works in this country.

## ELECTRIC VEHICLES

At a recent meeting of the Electric Vehicles Committee it was decided to issue a quarterly official journal, which will be sent free to municipal and other authorities, and supply departments will be able to purchase further copies for distribution. A series of advertising cards is also being prepared.

The Committee has now issued details of the design of the concentric charging plug which they have submitted to the International Electrotechnical Commission with a recommendation for its standardisation. Sections of the plug and receptacle are shown in Fig. 1, with full dimensions. The outside contact is to be used as positive and the inside negative. The terminals are to be large enough to receive 0.15 sq. in. cable, and are to be marked + and -. It is recommended that the receptacle on the car be placed under the driver's seat, so that he cannot take his seat before the plug is withdrawn. The rated capacity of the apparatus is 150-amperes, but currents up to 300 amperes may be dealt

FIG. 1.—DETAILS OF STANDARD CHARGING PLUG AND RECEPTACLE.

porting spiders are complete in one piece. Among the various operations which struck us particularly was the pressing of the two flanges on the stem itself, which is done with great rapidity by an ingenious machine which is served only by one girl. Fig. 2 shows one of the sealing-in machines, for sealing the wound stem

with for short boosting charges. The earthing arrangement is clearly shown on the drawing, and the earthing conductor in the flexible cable should be equivalent to 7/16 S.W.G. The shells of both plug and receptacle are to be of mild steel tube, the bracket and cap of malleable cast-iron, and the contacts of gun-metal. Two alternative sizes of terminals and cable grips are recommended for standardisation, viz.,

for main conductors 1.10 sq. in. (overall diameter of three-core cable 1.5 in.) and 0.075 sq. in. (overall diameter 1.31 in.). The larger size is for Edison batteries requiring heavy boosting charges, and the smaller for lead batteries. It is recommended that "cab-tyre" sheathing be employed on the flexible cable. Further details are contained in a complete specification obtainable from the Committee. An example of a plug and receptacle made in accordance with the Committee's specification by A. Reyrolle & Co. (Hebburn-on-Tyne) is shown in Fig. 2.

It has been decided by the Committee to appeal for funds for carrying on its work from electric supply authorities and manufacturers, and over £100 has already been received in this way. A standard design of sign for charging stations has been approved.

As to the measuring instruments which should be fitted to

FIG. 2.—REYROLLE CHARGING PLUG.

electric vehicles, the Committee are of opinion that in the case of lead batteries both a voltmeter and an ammeter should be provided. Where, however, the battery is not removed for charging, and in cases where no constant attendance is provided during this operation, it is recommended that an ampere-hour meter should be provided, in addition to the ammeter, with provision for automatically opening the circuit when the battery is fully charged. In the case of batteries of the Edison type, an ampere-hour meter is the only instrument which need be provided. The Committee consider also that a mileage recorder is a necessary accessory for judging the condition of the battery in conjunction with the electrical instruments, and for preserving accurate records of the working of the vehicle. The Committee have been informed that mounting these instruments direct on the dash-board has not proved satisfactory hitherto, and the latest practice in America is to have them fixed on a strong steel pillar well in view of the driver, and distinct from the dash-board.

## ELECTRIC TRACTION NOTES

The Board of Trade Report upon accidents on railways in the United Kingdom during 1913 draws special attention to the use of electricity in preference to gas in railway carriages, and also to the necessity for adopting means to safeguard against mistakes by signalmen and drivers. Regarding the latter, a memorandum was prepared towards the end of last year by the inspecting officers and submitted to the various railway companies urging them to extend the use of electric track signalling in connection with the control of signals or block instruments, and to carry out combined experiments with different systems of cab signalling and automatic control with the object of supplementing the present system of semaphore signalling. The inspectors hold the view that some such system as cab signalling, or wireless or inductive control, should be generally adopted in the future, whilst the inspectors are now insisting upon the use of the track-circuit system in regard to new works where the traffic is dense, or there is a frequent service of express trains. On the question of train lighting some of the larger companies have

adopted the Board's suggestion of substituting electricity for gas on main-line and express trains, but the proportion of rolling stock of the sixteen chief companies lighted by electricity is still not more than one-fifth. As is known, a large proportion of the rolling stock used for suburban traffic is lighted by electricity.

## OPENINGS FOR THE EXTENSION OF OUR ELECTRICAL EXPORT TRADE

IN our issues for August 27th, page 475, and September 3rd, page 485, we went, in some detail, into the openings for the extension of our electrical export trade, which the cessation of German exports since the commencement of the war has rendered possible.

From subsequent information furnished by the Board of Trade Intelligence Department it appears that applications have been received from inquirers desirous of purchasing the following: Batteries, carbons, bells and pushes, lighting and accessories, corrugated iron cases for transformers, insulating links for switches, general fittings, dynamos and motors for automobiles, zinc cells, brass caps for flash lamps, celluloid cases, enamelled copper wire, magnets, magnetos, papier-mâché covers, vulcanite mouldings, incandescent lamps, arc-lamp carbons, vessels for electric accumulators, china and earthenware for electric fittings, machinery for making electric lamps, iron cases for transformers, electrical fittings, copper-coated steel wire for turbine blades. Application for names should be made to 73 Basinghall Street, E.C.

H.M. Consul at Milan has, since the outbreak of the war, received inquiries from Italian firms who have hitherto received the following classes of goods from Germany, but are now anxious to buy or import British products. These goods include all classes of electrical machinery, telephone material, and arc-lamp carbons.

H.M. Consul at Rio de Janeiro points out that the present condition of affairs affords British firms an excellent opportunity of securing much of the business hitherto handled by German houses in that city. Among the principal articles of German import have been large quantities of electrical plant and fittings of every description, and particularly have certain German firms been doing a lucrative business in connection with hydro-electrical installations. The necessity for giving long credit and also for sending representatives with a good knowledge of Portuguese to Brazil is emphasised.

## THE UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE day classes at the Northampton Polytechnic Institute commence on September 28th. The evening courses commence on September 21st, and the important departure made a year ago by the introduction, as part of the regular courses, of lectures by specialists in various subjects is to be developed. Thus in the electrical engineering department there will be advanced lectures on "Transformer Design," by Mr. W. C. Kennett, and on "Electrical Instruments and Switchgear," by Mr. A. C. Heap.

The Manchester Municipal School of Technology commences its part time (evening and apprentices day) courses on Monday, September 28th. These include electrical and mechanical engineering, mining, &c.

A Proctor Baker Scholarship, tenable in the Faculty of Engineering, at the University of Bristol, has been awarded by the Society of Merchant Venturers to Mr. D. A. Gough. Merchant Venturers' Scholarships, also tenable in the Faculty of Engineering, have been awarded to Mr. E. S. Britton, Mr. E. A. Cockett, Mr. H. C. Collis. Messrs. F. H. Bulloch, H. H. Stewart, and A. Viswanath have passed the supplementary intermediate examination for the B.Sc. in engineering, and Mr. C. W. Taunton has passed the supplementary examination for the certificate in engineering.

The course of study in electrical engineering, extending over three or four years, at King's College, begins on Wednesday, September 30th. Among the special lectures arranged are the following:—"Electrical Engineering with reference to its Commercial Aspect," by J. S. Highfield, ten lectures, commencing October 4th; "Central Station Practice in its Relation to Legislative Enactments," by C. H. Wordingham, ten lectures, commencing January 15th, 1915.

**Telegraph Notes.**—Communication with the Republic of Colombia was restored on the 16th inst.—The Ottoman Government has prohibited the use of wireless on ships in territorial waters.—The Norwegian Government has put into force Article 8 of the Telegraph Convention regarding restrictions of service, and the Portuguese Colonial Minister has prohibited the use of secret language in telegrams to Huila in Angola or transiting *via* that place.—Messages must be written in plain Portuguese, French, or English.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,410.

Please explain fully why, with three single-phase transformers connected "star-star," it is impracticable to take any load between phases and neutral on the secondary side. What effect has the earthing of the neutral point of the primary windings on this?—"POWER."

(Replies must be received not later than first post Thursday, October 1st.)

### ANSWERS TO No. 1,408.

It is desired to run two rotary converters in parallel from an A.C. generator with a single winding. An essential part of the scheme being that each rotary can be started or stopped independently of the other. As part of the generator output is required for transmission purposes, two separate windings, one for each rotary, cannot be considered. The D.C. output is required for lighting or traction. Would it be necessary to use a transformer or reactance with one rotary, or would it be possible to run the rotaries in parallel on both A.C. and D.C. ends? If the latter scheme is undesirable, as seems to be the case, what are the reasons?—"ROTARY."

The first award (10s.) is given to E. P. HOLLIS, whose reply in a slightly abbreviated form is given below:—

When first it was attempted to operate rotary converters in parallel on both the alternating and the continuous-current sides, difficulties were met, with the result that up to quite recently no attempt has been made so to operate converters. When a number of rotary converters are connected in parallel on their alternating and continuous-current sides, there exists between

TWO ROTARY CONVERTERS SUPPLIED FROM ONE SIX-PHASE GENERATOR. CURRENTS BALANCED BY MEANS OF PATENT BALANCING COILS.

each phase bus-bar and the continuous-current bus-bars a number of parallel paths of low resistance. The resistance of these paths is made up of the resistances of the connections, converter armature, and the brush resistance. The total is low, but the brush resistance composes a large part of the whole, and is a variable quantity. The current distributes itself according to the resistance of each circuit, and it is found that uneven

distribution of the current takes place. One finds that the positive side of one converter is often feeding very much more than the negative side of the same converter, possibly throwing a large overload on to another converter in parallel with which it is working, and bad parallel running results.

In the early days, when rotary converters had only to be operated from transformers, and not direct from generators, the difficulty was easy of solution, and it has become a standard practice to feed each rotary converter from a separate transformer or to feed a group of rotary converters from separate secondary windings of a transformer with one primary. Recently, however, another circumstance has raised itself which has again brought under consideration this characteristic of rotary converters, namely, the operation of rotary converters in parallel direct from a turbo-generator alternator, where a continuous-current turbo-generator is not practicable. In this case the alternating-current generators supply low-pressure, six-phase current. It is preferable that each turbo-generator be provided with at least two rotary converters, but the result is that the old problem of parallel running is again raised. The obvious solution was that which served satisfactorily in the case of the transformer, namely, to give the turbo-generator two windings. In many cases this introduces no difficulties, but, as is suggested in the question, sometimes other circumstances make two windings undesirable. To eliminate the two windings, a method has been patented (Patent No. 11,905/13 of A. H. Railing and C. C. Garrard) which provides a satisfactory solution. In this method, differentially wound balancing transformers are inserted in the low-tension A.C. leads of the rotary converters, as shown in the diagram in the figure. These balancing transformers consist of two windings on the same core, and one transformer is inserted in each of the three phases of the three-phase rotary converters or for six-phase rotary converters, as shown in the diagram. The two coils of each transformer are wound in opposite directions, and the alternating current supplying one phase of one converter is passed through one coil, and that of the same phase for the other converter is passed through the second coil. Consequently, when the currents are equal they cancel out, but should one converter attempt to take more than its share of the load, the excess of current magnetises the core and induces an electromotive force in the other winding, which assists the current flowing therein, and tends to cause that current to increase until the two currents flowing are again equal. In this way the loads taken by the rotary converters are equalised, and the unbalancing of current brought about by the circumstances related is entirely obviated. Any number of rotary converters can be operated in parallel on this principle, and, in addition, it would be possible to take part of the generator output for transmission purposes, as suggested in the question. [Mr. Hollis also encloses photographs of balancing coils made for this purpose.]

The second award (5s.) is made to E. P. HILL, who writes as follows:—

The point at issue consists in the possibility or otherwise of installing two rotary converters to obtain independent lighting or traction service (alternatively with parallel running) without providing each rotary with a separate transformer or reactances. As part of the supply is required for transmission, the generator is probably a high-voltage alternator, and a transformer is requisite in any case for the rotary supply, and the difference in cost between two separate transformers and one large one is small compared with the increased reliability obtained. On the assumption, however, that for some reason the alternator is a low-voltage machine, there are several practical considerations which decide the best course to adopt in any particular instance.

Modern rotaries are usually multiphase, very generally six-phase, machines on account of the lower heating losses and better commutating qualities. This in itself necessitates the intermediary of transformer, and will be found a good investment in the long run. Again, as the machines are to be over-compounded, the reactance necessary to obtain this is best obtained by adapting the leakage of the transformer for the purpose. The question of starting is very conveniently accomplished by a low-voltage tapping on the transformer which will allow rotary to run up and fall into synchronism automatically. The result of unfortunate experience in the attempt at parallel running of rotaries at both ends direct from an alternator or off one bank of transformers has caused the practice to be avoided. Among other disadvantages is that the load does not divide evenly between positive arms or negative arms respectively, commutating conditions become bad, and sparking develops. Compound

rotaries, unless carefully damped, would tend to shunt badly if run as proposed, with deleterious effects on commutation. Should a full control of power-factor be required in the proposed scheme, a booster with shunt and series windings will give best results and enable a good regulation to be obtained on transformer. This booster between slip-rings and rotary winding is the standard arrangement in Great Britain for corporation supply where either lighting or traction has to be provided for on one rotary. Provision is often made to reverse the series winding on lighting to obtain a drooping characteristic.

## ANSWERS TO No. 1,406.

"Doubtful," who put this question, writes that he has tried, with success, a simpler solution than is advocated in the answers which we published in our issue of September 10th. He has cut out the series winding and employed separate excitation of the shunt windings, without further alteration. He thinks that the good results have been due to the compounding action of the interpole windings. "Doubtful" has been fortunate that this treatment answered in the case of his machine; in many machines he would have experienced commutation troubles and bad regulation.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published September 17th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

**Names in italics indicate communicators of inventions from abroad.**

**26,367/13. Carbon Holders for Arc Lamps.** H. AYRTON. The improved holders have for their object the enabling of the carbons to be turned down to a very short length without damage to the metal-work of the holder. In one form a screen of carbon or other material is used between the electrode and the holder, and in another pattern the electrode is drilled out to receive a part of the holder. Seven figures.

**29,070/13. Electrically Heated Utensils.** W. F. PERRY and CRENDEN CONDUITS, LTD. The base of the vessel is stamped with ridges and depressions which give it strength, while affording in the latter accommodation for the strip heating elements. Four figures.

**29,165/13. Telephony.** A. S. J. VAN KESTEREN. A telephone system employing repeaters for strengthening the current waves, and having a separate line for conversation in each direction. These two lines are connected at the ends to each other, and also to wires going to each subscriber's station, the latter connections being either positive or inductive, while the damping in the lines between the two points of connection is equal to or greater than the total strengthening produced by the repeaters.

**1,252/14. Metal Filament Lamps.** G. M. J. MACKAY. This specification relates to the use of phosphorous pentoxide within the exhausted bulbs of the lamps to prevent blackening. One figure.

**2,118/14. Electric Cooker.** G. PATE and A. R. WOOD (Carron Co.). This grillor comprises a carcase with upright sides formed with runners, and a rack. The heating element is slid into one pair of runners, and the grill pan is supported by another pair. Five figures.

**12,641/14. Traction Motor.** N. W. STORER. The motor is for high-tension continuous current, and has two armatures side by side in a rectangular case with inwardly projecting poles; each has two main poles, one commutating pole and one compensating winding. Two figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** GRAY and BEST [Arc lamps] 6,350/14.

**Distributing Systems, Insulating Materials, &c.:** HOWARD [Tiles for protecting cables] 21,446/13; LEACH and JOEL [Insulation] 26,149/13; RAFFI [Insulators] 13,784/14.

**Dynamos, Motors, and Transformers:** MENSFORTH [Dynamos] 22,149/13; A. G. BROWN BOVERI ET CIE. [Starting transformers] 12,012/14.

**Electrochemistry:** NIBLETT [Electrolytic apparatus] 24,559/13.

**Switchgear, Fuses and Fittings:** RICHMOND [Time switches] 19,676/13; ALDOUS & CAMPBELL, LTD., and ARCHER [Switches] 21,678/13; MARVIN [Motor control] 24,949/13; ENGELKE and BLOODWORTH [Adjustable resistances] 26,361/13; FINCATO [Re-

gulators] 1,238/14; SHEWARD [Fittings] 1,691/14; IGRANTO ELECTRIC Co. (Cutler Hammer Mfg. Co.) [Fluid rheostats] 1,786/14.

**Telephony and Telegraphy:** JOHNSON [Telephone exchange system] 20,011/13; ARNTZENIUS [Junction line and order wire working] 21,735/13; NEW PHONOPORE TELEPHONE Co. and NICHOLSON [Selective signalling] 27,018/13; FLEMING [High frequency generator] 3,963/14; BETULANDER and PALMGREN [Automatic selector] 16,619/14.

**Traction:** PECKHAM and THOMAS [Automatic tramway brake adjuster] 19,842/13; HARPER [Signalling] 21,428/13; ROMNS [Supporting tramway rails] 22,609/13; WELSH [Trolley wheels] 26,198/13; PEACOCK [Signalling] 26,638/13.

**Miscellaneous:** BARTRUM [Synchronising clocks] 12,432/13; CROSBEE, CROSBEE and ROGERS [Contacts for electric horns] 19,965/13; BLAKE [Vehicle for cable drums] 20,325/13; CLERC [Electric clocks] 25,977/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Instruments:** LEEDS [Potentiometers] 19,283/14.

**Telegraphy:** ROBERTS [Wireless receiver] 19,054/14.

**Miscellaneous:** BUNTE and REMMLER [Vacuum cleaners] 17,628/14.

### Amendments Allowed

**12,082/13. Arc Lamps.** H. AYRTON. A correction of a clerical error has been made in this specification, which is for a means of adjustment of the negative electrode of projector lamps in addition to the feed mechanism.

**14,816/13. Telephone Exchanges.** S. CONNER and A. R. KAHL. This patent has been amended by way of disclaimer.

### Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

**17,262/00. Electrolytic Meters.** A. WRIGHT and REASON MNE. Co. This patent covers the use of a mercury anode and a platinum cathode in electrolytic meters.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors and Transformers:** B. T.-H. Co. (G.E. Co., U.S.A.) [Voltage regulation] 11,535/05.

**Incandescent Lamps:** A. SWAN (G.E.C., U.S.A.) [Lamp caps] 12,739/02; W. SCHEURMANN [Exhausting pumps] 11,868/08.

**Switchgear, Fuses, and Fittings:** O. A. MYGATT [Reflectors] 10,662/09 and 13,082/09.

**Telephony and Telegraphy:** W. JUDD and A. FRASER [Electromagnetically controlled perforators] 12,458/02; MARCONI'S WIRELESS TELEGRAPH Co. and R. D. BANGAY [Condensers] 12,968/07.

**Traction:** T. VARNEY [Overhead conductors] 12,458/07.

**Miscellaneous:** MCNEIL and PEARSON FIRE ALARM, LTD. [Automatic fire alarms] 12,376/04; MARCONI'S WIRELESS TELEGRAPH Co. and R. D. BANGAY [Electromagnetic engine governor] 12,828/07; H. M. DARRAH and L. A. HACKETT [Sliding contacts] 11,758/08.

**The German Electrical Industry and the War.**—News has reached us *via* Switzerland that already at the end of last month an announcement was made by the A.E.G. that, in view of the shortage of hands due to the mobilisation, it was practically impossible to make any deliveries. Export was quite interrupted, and in such departments as that for large machines the few hands that were left were only working full time on three days a week, and five hours on the other three, but it had not been found necessary to discharge

hands on a large scale. In the departments where aero-planes and other war material are made, three shifts a day are being worked. It is also reported that the leading German firms, including the A.E.G., Siemens-Schuckert, and Bergmann, have withdrawn many existing price lists and announced in many departments increases in prices of 10 and 20 per cent. Probably the state of affairs has become materially worse since the information referred to was published.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Although the Metal Exchange is not open for business in the ordinary course, the following may be taken as the official quotation for electrolytic copper bars, viz., £54 10s. to £55. (Last week £55 10s. to £56.)

**British Trade with Italy.**—H.M. Consul at Milan telegraphs that the British Chamber of Commerce there has received inquiries from local firms who are desirous of purchasing large quantities of British goods, including dynamos, motors, iron and steel goods, and general machinery.

**Colonial and Foreign Agencies.**—An electrical company in the Province of Quebec, whose representative will shortly be visiting this country, is open to represent United Kingdom manufacturers in the following goods:—A.C. motors; half-watt and other forms of lamp fittings; lampholders; cut-outs and fuses; house wires; cables and flexible cord for electric cooking and heating apparatus; and electric fans.

An electrical engineer in Christiania (Norway), reports H.M. Consul in that city, desires to secure the agency for Norway of United Kingdom manufacturers of general electrical goods.

Further particulars in both cases at 73 Basinghall Street, E.C.

**Scholey & Co., Ltd.**—This firm write to correct a false impression, emphasising that they are a British organisation in every sense of the word. Scholey is one of the oldest family names in Yorkshire, and there is no one on their Board or staff who is associated with any German or Austrian family.

**United Softeners, Ltd.**—The Company ask us to

announce that they have no connection with Germany, no interest is held by Germans, and all their products are British made. The Directors are A. O. Burton, L. A. Neel, and S. H. Menzies (British), V. Hjorth (Danish), and J. J. Lassen (Danish, naturalised in Great Britain).

**Contraband.**—A Royal Proclamation notifies that copper (unwrought) and magnetic iron ore will be treated as conditional contraband during the war or until further notice.

### APPOINTMENTS AND PERSONAL NOTES

At a meeting of the Council of the British Electrical and Allied Manufacturers' Association, held at the offices on the 17th inst., Mr. B. H. Antill, Director and Manager of Siemens Bros. Dynamo Works, Ltd., was elected a member of the Council, in place of Mr. C. Koettgen, resigned.

The name of Lord Guernsey appears on the list of the Officers of the Guards who have been killed in action in France. Lord Guernsey was Chairman of Duram, Ltd., in which business he took an active part. At the commencement of the war he was a Captain of Yeomanry, but immediately rejoined his old regiment, the Irish Guards, as Captain.

A Generating Engineer is required by the Hackney Electricity Department. Salary £120, rising to £150 per annum.

A temporary Charge Engineer is required at Wakefield. Salary £2 per week. Applications to City Electrical Engineer.

A Test-room Assistant is required temporarily during the war, at Leith. Salary 35s. per week. Applications to Burgh Electrical Engineer.

A cable jointer is required in the Hammersmith Electricity Department. (See advertisement on another page.)

## "ELECTRICAL ENGINEERING" TRADE SECTION

### NEW ELECTRIC LIGHT FITTINGS

**T**OWNSHEND'S ART METAL CO., LTD. (Ernest Street, Birmingham), whose electric heating apparatus is already well known to our readers, has issued an extremely attractive catalogue of electric light fittings. Our illustrations, which show two of the smaller ones, do not do justice to the effectiveness of the many new designs of fittings shown in the list, which contains some pretty examples of brackets, hall lanterns, electroliers, pendants, and table standards, all at very reasonable prices.

### NEW ARC LAMP WINCH

**O**UR illustration shows a new winch got out by the London Electric Firm (George Street, Croydon) to meet foreign competition. It is made in two sizes for large and small lamps, and is a very robust and reliable construction.

The designer has aimed at omitting the weak and embodying the strong points of existing patterns. The price is low, and those desiring a cheap winch need not buy a foreign-made article.

### ELECTRIC HEATERS

**W**E are informed by the Bastian Electric Heating Syndicate, Ltd. (185 Wardour Street, W.), that they are now taking orders for heaters of their well-known A type, in sizes up to 2 kw. As at present constructed the heater is fitted with six Vitrolite glowers of 333 watts capacity each, and a switch is provided to reduce the rate of consumption to 1.8 kw. In this construction the "Tabasco" resistance wire is wound as a perfectly close spiral around the exterior surface of a quartz tube, the convolutions being prevented from short-circuiting one another by the oxide on the wire itself. This construction had many advantages, including that of cheapness, which enable the firm to put these heaters

on the market at the moderate price of 80s. each. They inform us that they are, at the present time, more busy than they have ever been before at this season of the year, owing to large orders on hand for heating apparatus for his Majesty's warships.

### THE EDISWAN RIFLE RANGE

**W**E illustrate here the interesting scene of the opening of the rifle range established by the Edison & Swan United Electric Light Co., Ltd., on September 5th. Mr. J. W. Elliott, Lamp Sales Manager, fired the christening shot

OPENING OF THE EDISWAN RIFLE RANGE.

and declared the range open. The range is on the Co.'s own premises, and arrangements are made for 25, 50, 75 yds. range. A large active membership is shown in the illustration, but there are many who were unable to be at the opening. It is proposed by the Committee to cover in the range during the winter months.

### CORRESPONDENCE

To the Editor of ELECTRICAL ENGINEERING.

SIR,—The Corona Lamp Works are making distribution of a circular purporting to give information as to "who's who" in the lamp industry. They are evidently doing this with the intention of suggesting that practically every lamp firm, except their own, is a foreign firm. To further this idea they give the names of directors of various firms, always being very careful to give only the foreign-sounding names, to suggest German nationality. Their spirit of fairness, however, leads them totally to ignore the names of all directors, &c., who are obviously British. Their action is strange in view of the fact that in May last a judgment was obtained against them regarding large quantities of lamps imported by them from the Continent.—Yours truly, ATLANTIC.

London, September 22nd, 1914.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**CAB-TYRE SHEATHING.**—A very attractive coloured leaflet on the advantages of their "cab-tyre" type of sheathing for hand lamps and other portable apparatus, has been issued by the St. Helens Cable and Rubber Co., Ltd., Warrington. This imitates the style of an illuminated address, and is most effective.

**Electrical Drive for Textile Mills.**—A very important contract has been placed with the General Electric Co., Ltd., of Queen Street, Belfast, by the York Road branch of the York Street Flax Spinning Co., for an electrical plant for the individual driving of spinning frames. This is one of the first installations of its kind in Ireland. The entire equipment will be manufactured at the Witton Works (Birmingham) of the General Electric Co., Ltd.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Bispham.**—The Council is to ask for a loan of £8,155 for electric supply purposes.

**Colombia.**—Messrs. S. Pearson & Son, who have entered into a contract with the Colombian Government for the improvement of Cartagena, have undertaken to instal an electric lighting plant.

**Hornsey.**—Two rotary- or motor-converters are required. Borough Electrical Engineer. October 9th.

**Kelso.**—Negotiations are being carried on between the Council and the Gas Co. with a view to the latter installing electricity generating plant.

**Littleborough.**—Transformer kiosk with equipment, including mains, high- and low-tension cable, transformers and switch-gear. Consulting Engineer, W. C. C. Hawtayne, 9 Queen Street Place, London. October 12th. (See an advertisement on another page.)

**London: Woolwich.**—Sir John Snell has advised the Council to take immediate steps to obtain further plant as the estimated demands during the coming winter will absorb all the existing spare capacity. The Council has, in consequence, authorised the purchase of a 3,000-kw. turbo-alternator at an estimated cost of £10,000.

**Lowestoft.**—The Borough Electrical Engineer has called attention to the fact that the question of increased boiler plant will have to be considered before long. He points out that the floor space occupied by the dry back boiler at present can be made to give double the evaporation by the installation of a water-tube boiler, whilst with the old boiler out of the way a greater efficiency can be obtained from the others by installing induced draught.

**Troon.**—The Kilmarnock Council hopes to be in the position to give a supply in this district by November. Parliamentary powers have just been obtained.

### Wiring

**Sheffield.**—Extensions at City hospital. City Architect, October 7th.

**Birmingham.**—Public baths, George Arthur Road, Saltley. Architects, S. N. Cooke and Twist, 117 Colmore Row.

**Blackburn.**—Fire station (£31,600).

**Derby.**—Free library, Pear Tree Road. Architect, C. B. Sherwin, 32 St. Peter's Street.

**London: L.C.C.**—320 wiring points at the Vallance Road Schools, Mile End. Chief Engineer, October 8th. (See advertisement on another page.)

**Pontypridd.**—Electric lighting of Llwynpia Homes. Clerk to Guardians. October 18th.

**Stoke-on-Trent.**—Telephone and bell installation at the workhouse.

### Miscellaneous

**Leicester.**—Tramway extensions estimated to cost £29,898 are to be put in hand.

**Oban.**—The Borough Electrical Engineer has been instructed to proceed at once with the conversion of all existing gas lamps in the principal streets to electric lamps.

**West Ham.**—Three months' supply of electrical fittings for the Guardians. October 1st. Clerk, Union Road, Leytonstone, N.E.

**York.**—The Tramway Manager has been instructed to obtain quotations for two electric omnibuses.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Bexhill.**—The Borough Electrical Engineer has been instructed to purchase 500 Edison and Swan metal-filament lamps.

**London: H.M. Office of Works.**—A contract has been placed with Messrs. J. H. Tucker & Co. for the supply, during the next three years, of 5 and 10 ampere tumbler switches.

**Oldham.**—The following tenders have been received for a D.C. motor-generator:—General Electric Co.; Lancashire Dynamo and Motor Co. (accepted); Electric Construction Co.; British Thomson-Houston Co.; Bruce Peebles & Co.;

Mather & Platt; Electromotors, Ltd.; Brush Electrical Engineering Co.; Siemens Bros. Dynamo Works.

**Swinton.**—A tender by the Lancashire Electric Power Co. for street-lighting equipment, at £1,800, has been accepted.

**Wolverhampton.**—The tender of the Davenport Engineering Co. at £2,620 has been accepted for cooling towers at the generating station.

Messrs. Joseph Kaye & Sons have received an order from the War Office for the immediate delivery of 3,000 patent seamless oil-cans. They have just delivered to the Navy 7,000 of these cans.

## LOCAL NOTES

**Belfast: Proposed New Power Station.**—In our issue for July 2nd, page 392, we mentioned that Sir John Snell had reported upon the general position of the electricity undertaking in conjunction with Mr. W. J. Pratten, formerly Manager of the Engineering Department of Messrs. Harland & Woolf. At that time Sir John Snell had presented an interim report which recommended the purchase of a 1,000-kw. rotary-converter in order to help the department temporarily. Sir John Snell's full report, which is just to hand, advises the Corporation on no account to remodel or permanently extend the existing power station, but to proceed with the erection of a three-phase high-pressure system. We will deal with the matter in greater detail in our next issue.

**Bristol: Electricity Accounts.**—The annual report and accounts of the Electric Lighting Committee were presented at the last meeting of the Corporation. We gave details in our issue for July 23rd, p. 426. In presenting them Alderman Pearson said that there had been an increase in every branch of the department, and the undertaking had been successful not so much because of any special merit on the part of the Committee, but through the efforts of the officials, who were keenly alive to their duties. He regretted the necessity of having to curtail in some degree the arc lighting, due to the policy of this country buying in the cheapest market, which policy was working rather badly for us to-day, as it had resulted in the carbon manufacturing business going almost exclusively into the hands of Germany. The Corporation had four months' stock in hand, and he hoped this example would be a lesson to all of us, that there is an advantage in supporting home industries, even though we have to pay a little more for them.

**Dundee: Bulk Supply.**—The Tayside Electric and Gas Light Co. has asked the Corporation for terms for a supply of electricity in bulk to be distributed in Wormit. Some objection was taken at the last meeting of the Corporation, when it was announced that it would cost £3,000 to lay the cables. It was subsequently decided to offer current at the Dundee boundary, leaving it to the Tayside Co. to carry out the necessary transmission from there. The idea of the Company was to pay interest on the cables, and so much per unit. The scheme would involve carrying cables across the Tay Bridge, and Mr. Richardson expressed the opinion that it would be necessary to take two cables across in order to provide against the possibility of one breaking down.

**Edinburgh: Electric Supply Profits.**—In view of the special circumstances now existing the Electric Lighting Committee has agreed unanimously to recommend that the whole of the surplus last year on the undertaking shall be applied to the relief of rates. The sum available is over £3,000.

**Keighley: Criticism of Electricity Charges.**—During a discussion upon the accounts of the Corporation Gas Department last week, in which a decrease of nearly six million cubic feet in sales was recorded, the Chairman of the Gas Committee said that the loss was chiefly attributable to the practice of selling electricity for lighting in mills, &c., at power rates, a practice which, he said, could not be too strongly condemned as being a great source of loss to the Corporation and unprofitable to the electricity undertaking. The Chairman of the Electricity Committee, in replying, said he regarded the statement of the Chairman of the Gas Committee as a splendid compliment to the Electricity Department. The policy of the Electricity Department was not to charge their consumers more than the value given, and then give the profit back to those who did not take electricity—a hint to the Gas Department not to make large profits and give large sums to relief of rates.

## SUMMARY

AN account is given of the equipment of a rolling mill which has been converted from steam to electric drive. (Page 524.)

A PAPER by Dr. L. Guillet, which was to have been read at the autumn meeting of the Iron and Steel Institute, and dealt with the preparation of electrolytic iron, is published in abstract. (Page 524.)

A BOOK on Mining Electrical Engineering is reviewed. (Page 525.)

TWO electrometallurgical patent specifications of interest relating respectively to recovery of metal from solutions and electric zinc furnaces were published during last month. (Page 526.)

A SCHEME for defence by live wires is put forward in our Questions and Answers columns. (Page 526.)

AN article by Mr. E. P. Hill gives some useful points with regard to the starting of rotary converters. (Page 527.)

SIR JOHN SNELL and Mr. W. J. Pratten have both recommended the Belfast Corporation to erect a new three-phase high-tension power station in preference to extending the existing works. (Page 527.)

THE British Engineers' Association has protested to the Government against the terms of the "Trading with the Enemy" Proclamation, and urges that firms in this country having relations of any sort with Germany and Austria should be treated as alien enemies. (Page 528.)

THE Institution of Electrical Engineers has been carrying out practically all the work connected with the raising of five hundred men to serve in the Divisional

Engineer Units and Signal Company of the recently formed Royal Naval Division. The Institution has also been instrumental in obtaining temporary work in central stations for men out of employment ineligible for military service. (Page 528.)

EXPERIMENTS have been carried out at Hove with different types of trolley omnibuses. (Page 528.)

A METHOD of controlling fog signals by wireless is mentioned under Telephony and Telegraphy. (Page 528.)

AMONG the specifications published by the Patent Office last week is one for stranded steel commutator connectors for turbo-generators. Other subjects are thermal current regulators and searchlight lamps. Application has been made to suspend foreign patents for ignition devices and magnetic clutches. The patent for a thermo-galvanometer is expiring. (Page 529.)

OUR Trade Section contains illustrated descriptions of a cinema equipment and a recent form of electric heater. (Page 530.)

WE publish correspondence regarding the B.E.A.M.A. and the war, a letter from an Antwerp firm desiring agencies, and a statement as to supplies of arc lamp carbons from Switzerland. (Page 531.)

TURBO-ALTERNATORS, water-tube boilers, etc., are required at Colwyn Bay, and electric lamps at Stockport.—An electric lighting scheme is under consideration at Eastleigh.—Electrical fittings are required for an asylum at Edinburgh. (Page 531.)

THE Dewsbury Electricity Committee has refused to consider a bulk supply scheme from the Yorkshire Power Co.—Applications for sanction to erect overhead wires have been made by the York Corporation, the Blackrock Councils, and the Clevedon Electric Supply Co.—The domestic power demand in St. Anne's-on-Sea has doubled itself in the past twelve months.—There was a loss of £6,162 upon the Stoke-on-Trent electricity undertaking last year. (Page 532.)

AN 8 per cent. dividend is announced by the British Insulated & Helsby Cables, Ltd.; 6 per cent. by the British Electric Transformer Co. and by the British Aluminium Co.—on the preference shares in the latter case.—A satisfactory half-year's trading is reported by the Clyde Valley Electrical Power Co., but no dividend is announced. (Page 532.)

## TECHNICAL COLLEGE ANNOUNCEMENTS

A considerable number of scholarships are offered in connection with the trade schools of the London County Council. Application must be made to the Education Officer for entry forms (No. T2-258) not later than October 17th, and the examinations will be held in December.

WE have received a prospectus from the Electro-technical Bureau (Campfield Chambers, 312 Deansgate, Manchester), where correspondence courses in electrical engineering are conducted. The course, besides the general sections on continuous-current and alternating-current engineering, include special sections on electrochemistry, electric traction, electricity in mines, power-house working, and electrical machine design.

# ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

## AN ELECTRICALLY DRIVEN ROLLING MILL

NOT only is there a general tendency to equip every new rolling mill with an electric drive, but in many cases steam engines driving mills are being replaced by electric motors. In a recent example of a conversion from steam to electric drive, the mill was previously driven direct by a

FIG. 1.—300 H.P. MOTOR DRIVING ROLLING MILL.

horizontal steam engine at about 60-70 r.p.m. It has three-high roughing rolls and two-high finishing rolls and guide train. The work consists in rolling iron and steel billets varying between 120 and 200 lb. weight down to flat rounds, &c.

To convert to electric drive, the steam engine was removed and replaced by a 30-ton flywheel, coupled to the mill shaft

FIG. 2.—SWITCHGEAR AT REAR OF MOTOR HOUSE.

and rope-driven from a 500-volt continuous-current compound-wound "Witton" motor of 300 h.p., running at an average speed of about 220 r.p.m. To enable the flywheel to do its share of the work the motor was compounded so as to have approximately a 20 per cent. drop between no load and full load. As will be seen from the accompanying illustrations, Figs. 1 and 2, a light wooden motor-house was placed round

the motor, and one side was removed for the purpose of taking the photographs.

The motor is controlled by a switch panel from the rear of the house. This panel is provided with main switch, circuit-breaker, ammeter, speed regulator, and multiple switch starter. With the exception of the circuit-breaker, which is at the top of the board and out of reach, all the switchgear is fitted with protecting covers. The switchgear is interlocked, so that the circuit-breaker, switches, and starter must be operated in the correct sequence, whereby accidents are prevented. Any attempt to close the circuit-breaker after one of the starter switches has been closed is frustrated, so that the switchgear is completely mistake-proof. In addition to this switchgear a push-switch is provided near the rolls by which the motor can be stopped in an emergency.

One of the owners, speaking before an important engineering society, recently said:—

"There has not been a single hitch of any kind whatever, and the results were even more satisfactory than were anticipated. There had been great economy of floor space. . . . As a matter of fact, the electric drive occupied less than half the space of the previous steam engines. A great saving had also been made in the power consumed. Those engaged in the management of iron and steel works knew what power could be consumed by the screwing down of the screws in the housings to keep the rolls in position. It happened not at all infrequently that a steam engine could not start them because these screws were down so tight, and they had to be eased before the engine would start. The same thing applied equally to a motor, but it was possible to tell by the use of the ammeters what power was being used, and whether the men were looking after their work properly. . . . It was found (with the motor) that an increase of 20 per cent. in output was obtained . . . partly due to the greater regularity with which the train was driven, and further than that, the quality of the work was better, due to the more regular speed which gave a more regular size of bar rolled. There was also a considerable economy in the matter of labour and in lubricating materials."

The energy for driving this motor is generated from exhaust steam, so that the power is obtained very cheaply. The electrical plant driving this mill was supplied by the General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, London E.C.).

## ELECTROLYTIC IRON

AMONG the Papers which were to have been read at the autumn meeting of the Iron and Steel Institute was one by Dr. L. Guillet, of Paris, on the manufacture, properties, and uses of electrolytic iron. Although as far back as 1860 Klein in Petrograd used electrolytic iron for plates for printing bank-notes, and several subsequent experimenters developed processes for the preparation of electrolytic iron, it was not till lately that any emerged from the laboratory stage. Now, however, a commercial plant has been laid down by one or two French firms under the "Le Fer" patents. In this method a revolving cathode is used with a solution of iron salts maintained in the neutral state by circulation over the surface of the iron. The bath also receives periodic additions of a depolarising medium such as oxide of iron, the object of which is to eliminate, at least in part, the hydrogen deposits on the cathode, which injuriously affect the material if present in too large a quantity. By these means it is possible to work with a current of high density (1,000 amps. to the square metre), and an iron of excellent quality is obtained. The process is applicable either to the production of very pure iron, which can compete with best iron and Swedish iron, or to the direct manufacture of tubes and sheets in the finished state. Two tons of metal per kw.-year can be obtained, including current for all auxiliary purposes. At present the process is mainly used for making tubes round a mandrel which is easily withdrawn after annealing. At the works of Bouchayer and Viallet over 100 tubes four metres in length in sizes up to 200 mm. diameter can be turned out per day. When removed from the bath, the material is hard and brittle, and shows a peculiar microscopic structure, owing to interstrain and occluded gases, but after annealing

are STILL THE BEST for retaining perfect insulation in the windings of all Electrical Machinery, so there is no need to experiment with *unknown* materials

Standard Specialities are *regularly* used by the leading Electrical Manufacturing Firms, Lighting and Power Stations, Railways, Tramways, &c., which constitutes definite proof of their *practical* utility.

Catalogue and Expert Advice  
where necessary from

PINCHIN, JOHNSON & Co., LTD.

Minerva House, Bevis Marks, LONDON, E.C.

at 800° to 900° C. shows normal micrographic structure, and can undergo deformation to an extraordinary degree without fracture. Its properties are discussed at some length in the Paper.

The industrial applications of electrolytic iron include, besides the manufacture of tubes and sheets, the preparation of pure iron as a raw material intended for fusion and rods of pure iron for autogenous welding. Tubes can be made without difficulty of a thickness of more than 6 mm., but for thinner tubes it is difficult to obtain a regular thickness. The tubes will stand high pressures exceedingly well. Plates suitable for stampings for electrical plant can be prepared of very high magnetic quality, compressive strength, and even thickness. A German authority has estimated that in transformers a saving in weight of 33 to 40 per cent. can be obtained by employing such material, and the capacity of A.C. motors can be increased by 50 per cent. and of D.C. motors by 16 per cent. These figures seem rather optimistic, and no mention is made of the ageing quality of the material. Electrolytic iron could compete successfully as regards quality with Swedish iron as a raw material for fusion, but its cost would probably work out at from £6 to £7 12s. per ton, according to the locality.

### REVIEW

**Electrical Practice in Collieries.** By D. Burns. 353 pp. 7½ in. by 5½ in. 172 figures. (London: Charles Griffin & Co., Ltd.) 4th edition. 7s. 6d. net; abroad, 8s. 2d.

This is the fourth edition of a work addressed to colliery managers, under-managers, engineers, and students, and gives a general survey of the electrical principles and applications of electrical power to colliery work. It does not pretend to go deep into highly specialised branches of the subject, and the very old-fashioned nature of some of the plant represented in the illustrations is not necessarily detrimental to the attainment of its object of conveying a general understanding of the matters treated of. In a subject advancing so rapidly as electrical colliery engineering it is probably easier to write a new book than to revise an old one, and despite the presence of some excellent new material there is a little lack of proportion, and here and there a little inconsistency in the result. Occasionally, too, the author has inadvertently left in descriptions of obsolete apparatus. The osmium lamp, for example, is mentioned as a modern metal-filament lamp; the types of arc lamp which are quite superseded still figure in the lighting section. Again, although the latest Home Office regulations are quite rightly included in the book, some of the illustrations, especially of haulage plants, show old open-type motors that could not possibly be allowed underground. We would also like to have seen modern types of colliery switchgear treated at much greater length. There is, however, much that is useful and practical in such chapters as those on motors, pumping, haulage, and coal cutting, the last of which is gone into pretty fully; but some of the best matter is hidden away in a regrettably short final chapter entitled "Miscellaneous Appliances," to which the most recent forms of electric miners' lamps, electrical shot-firing, and even main shaft winding are relegated.

**The Association of Mining Electrical Engineers.**—The Annual General Meeting of the Association will be held on Saturday next, at 4.30 p.m., at the Grand Hotel, Sheffield. The following are the nominations by the Council of Officers for the next session:—*President*, Mr. R. Holiday (Acton Hall Collieries); *Vice-Presidents*, Mr. A. Hall (Silverdale Co., Staffs.) and Mr. M. Brown (Banknock Coal Co., Glasgow); *Treasurer*, Mr. C. F. Jackson (Eshall Colliery, Nuneaton). The annual report records a membership of 1,170 among the ten branches of the Association, and the holding of many meetings for the reading and discussion of papers. At the examinations held last March, out of thirty-seven candidates thirty-one passed for first-class certificates, and all the remainder for second-class certificates. Finally, the report says: "The Association continues to make satisfactory progress in educational value and numerically, but the Council consider that the important work undertaken by the Association should receive much greater support from the Mining Industry."

**The Greenock Electrical Society.**—We have received a full programme of meetings for the ensuing session from the Greenock Electrical Society. Twenty meetings are arranged, the first of which is held to-day, when a paper on "Cottonopolis and its Electricity Supply" will be read by Mr. F. H. Whysall. The Honorary President of the Society is Mr. A. Robertson (Greenock and Port Glasgow Tramways Co.), and this year's President is Mr. D. McDougall (Greenock Corporation Electricity Department). There are over 130 members.

## MINING AND METALLURGICAL PATENTS OF SEPTEMBER

NO specifications of special interest to mining electrical engineers have been published by the Patent Office during the past month, but the following two deal with applications of electricity in the metal industries. In No. 19,669 of 1913, V. C. Tainton and M. F. L. A. Aymard (South Africa) describe an apparatus for electrolytically recovering metals from solutions, with a specially constructed filtering diaphragm composed of finely divided conducting material arranged on a conducting frame. The other specification is No. 10,061 of 1914, in which A. L. J. Queneau (Jemappes, Belgium) describes an improved electric furnace for the reduction of zinc, provided with condensers in the walls consisting of rows of pipes mounted at a suitable inclination.

### QUESTIONS AND ANSWERS BY PRACTICAL MEN

#### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

#### QUESTION No. 1,411.

I should be glad to know the best way of arranging to measure the winding ratios of transformers by potentiometer.

An example would be a 500 k.v.a. three-phase delta-star 6,600/356-volt, 50-period transformer. I believe this method of testing is employed by some transformer manufacturing firms.—W. C. K.

(Replies must be received not later than first post Thursday, October 8th.)

#### ANSWERS TO No. 1,409.

It is desired to erect around a city two miles in diameter a system of barbed wire charged at 3,000 volts as a protection against assault. Two three-phase generators, each capable of supplying 5,000 kw. continuously at this pressure, are available. Suggest the best design for the network, and the method of connection and arrangements of cut-outs, taking all the circumstances into consideration, including the necessity of automatically cutting out a section of the wire temporarily, if earthed, to save burning out the generators, and so cutting off the pressure

from the whole network, and, if possible, the automatic replacement of cut wires.

M. YOUNG (to whom an award of 10s. is made) sends the following suggestions:—

As shown below, two banks of barbed wire are supported on wood frames and insulators. Each bank is live to one phase of the generator through a special water-resistance. The third phase is connected to a two-inch water-main which sprays hard water or brine. A short or earth on any section will not be dead, but through the water-resistance. The balanced tube electrode is closed at the top, and will drive itself clear of the water by means of steam generated in its interior. Thus it acts as a time lag switch as well as a resistance. This resistance can also be used as a remote control worked by means of the insulated suspension cord.

The several rows of barbed wire are made live from the centre wire. The size of connecting links are graduated from No. 16 copper at the centre to No. 22 at the outside. This might clear a short on the outer wires and still leave the centre alive. Besides damping the ground, the live water-spray would prevent approach to the wires. These defences could be erected in hundred yard lengths.

No second award is made.

**Corrosion of Condenser Tubes.**—An article by E. Bate in the *General Electric Review* deals at some length with causes leading to the pitting and corrosion of condenser tubes. These causes may be briefly stated thus, stray currents from grounded systems, galvanic currents between the dissimilar metals of which the condenser is constructed, galvanic currents due to deposits of active material inside the tubes, use of unsuitable mixture for the material of the tubes. The increasing use of negative boosters on grounded systems prevents the first-mentioned point from being of serious importance. Regarding the second point, the alloy of which the tubes are usually composed is electro-negative to the cast-iron casing, so that no corrosion of the tubes could be caused by these currents. That the third cause is responsible for the greater majority of tube failures is borne out by the fact that 96 per cent. of the tubes examined by the author were pitted in the lower half, where, of course, all internal deposits would collect. It is suggested that in cases where the circulating water is drawn through a long line of cast-iron piping, oxide of iron and carbon may be deposited in the condenser tubes, thus giving rise to injurious electrolytic action. The author is of opinion that, once local corrosion has commenced, it cannot practically be stopped. A suggested method of preventing this deleterious deposit in the condenser tubes is to treat the interior of the cast-iron piping so as to prevent corrosion, and to keep the intake pipes as short as possible.

**Electrical Employees and the Army.**—About 25 per cent. of the total staff of the County of London Electric Supply Co., repre-

senting 75 per cent. of those eligible, have left for war service. The Company have arranged to keep the whole of the men's places open for them, and to continue pay, and special arrangements have also been made to assist the wives and dependents of all members of the staff on service.

Up to the present 453 men, equivalent to 20 per cent. of the British Aluminium Co.'s employees, have joined the fighting forces including men from the Kinlochleven, Larne, Milton, and the head office. Their places are being kept open, temporary provision being made in the meantime by drawing men from industries which are slack. Financial provision is being made for the staff in accordance with their responsibilities, and the families of all married employees serving with the Colours, or others dependent upon them, are being paid 10s. weekly, those residing on the Company's premises are permitted to do so rent free for the present.

## PRECAUTIONS IN STARTING ROTARY CONVERTERS FROM TRANSFORMER TAPPINGS

By E. P. Hill

THE rotary-converter has become such a useful and necessary servant to the modern electrical world that little apology is required for bringing forward information useful to the large number of users of this class of machine. Neglect of one or other of the following precautions may be the cause of serious trouble. The method of starting by low voltage-taps from the transformer is applicable only to machines up to about 300 kw., the difficulty on larger sizes being the disturbance of supply from the large wattless current drawn during the initial starting period. There is, in addition, the trouble that the polarity to which rotary will build up is subject to no control whatever, and must be reversed should it build up incorrectly. This latter point is in practice not productive of much difficulty, as a field change-over switch can be used, and there is, in addition, always the possibility by opening the main switch momentarily of rapidly reversing the polarity by slipping a pole. The main poles of the converter are fitted with grids, which act as the squirrel-cage rotor of an induction motor, and, together with the iron loss in the pole shoes, produce sufficient torque to bring the armature up to approximate synchronous speed. When the field switch is closed, the machine builds up and pulls into step on the low-voltage side of the changeover switch, and on the switch being thrown over, full voltage is applied, the rush of current being controlled entirely by the amount of reactance in the transformer circuit.

Should the machine be fitted with commutating poles, it

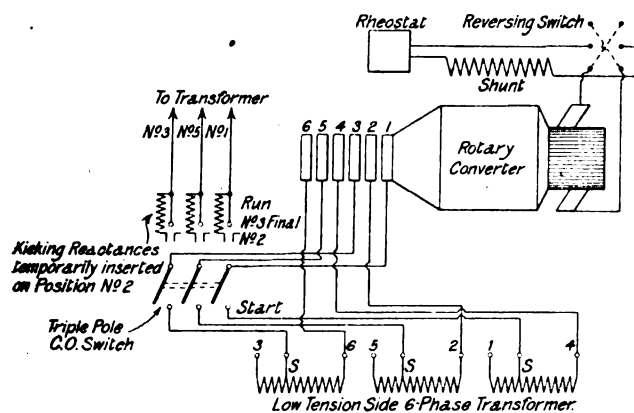

DIAGRAM OF CONNECTIONS FOR TAP STARTING OF 6-PHASE ROTARY CONVERTER.

is necessary to short-circuit them during starting to prevent the rotary "locking" at half-speed, that is, behaving as if it had twice its real number of main poles. If this precaution be neglected, a much slower start obtains, and sparking trouble occurs on the D.C. brushes. Again, the fact that the machine is only running at half speed may easily be overlooked, and, on switching over after the usual lapse of time, a flash-over occurs. It is advisable to wait on the starting side until the phase swinging dies down before changing over. Frequently surges in the supply (especially in traction circuits) cause a few seconds to elapse before a steady condition is reached, and after being instructed, an attendant, by the characteristic note, can tell when the time for switching over has arrived, and so avoid a flash on the commutator, and other ill effects. When the machine has to meet stringent guarantees of voltage regulation and efficiency the reactance necessary to limit current rushes has to be temporarily inserted during starting period by means of a kicking contact on change-over switch, as shown in the figure, attendants are tempted to throw over the switch on to the final position without pausing, as is intended, on the kicking contact. A stop is sometimes provided to ensure correct working, but some makers prefer to leave this to the discretion of the attendant in case he should, by the use of stop, burn out the grid resistances. A pause of from one to two seconds should be made on the kicking contact, when it will be found that a very satisfactory start results.

The brush friction loss of tap-started rotaries has considerable influence on the time taken to come up to speed. An unskilled attendant becomes very alarmed by the fact that the machine will not come up to speed, whereas a wipe of the commutator with a little lubricant will at once rectify matters. Too heavy brush tension or a rough commutator will cause

this trouble, but probably the transformer tap is too low when this symptom occurs.

In addition to the foregoing peculiar to rotaries of this kind, it is necessary, of course, to be alive to the usual maintenance precautions of ordinary D.C. and A.C. machinery of this description, in order to get the best out of what is without doubt an excellent piece of electrical plant.

## PROPOSED NEW BELFAST POWER STATION

### Three-phase High Tension Recommended

FOR the past two years it has been realised that something approaching a reorganisation of the Belfast electric supply undertaking was necessary in order to keep pace with the rapid growth in the demand. It cannot be complained that the Corporation has acted with precipitancy in the matter, for the question was under serious discussion during 1912 when a scheme for a new power station prepared by the City Electrical Engineer, Mr. T. W. Bloxam, was submitted to Mr. S. L. Pearce, Chief Electrical Engineer to the Manchester Corporation, who gave it his approval. Simultaneously a proposal was made by the Tramway Manager that Diesel engines should be installed in the existing power station for the purposes of the tramway undertaking, but this scheme did not meet with favour. Later on a deputation of ratepayers waited upon the Corporation and urged delay on the ground that Messrs. Harland and Woolf were developing a new type of Diesel engine, and that this might prove to be more economical than steam turbines. Our own inquiries at the time, however, showed that Messrs. Harland and Woolf were merely experimenting with the engine in question, and that its manufacture had not been entrusted to any of the three makers of Diesel engines well known in this country to our readers, but had been placed in the hands of a large firm of shipbuilders in Copenhagen with whom Messrs. Harland and Woolf have working arrangements. From early in 1913 and until a few months ago the proposal did not make any material progress, but in June Sir John Snell and Mr. W. J. Pratten (formerly Manager of the Engineering Department of Messrs. Harland and Woolf) were called in to report. These reports were referred to briefly on page 522 of our last issue, and we now review them in greater detail.

The two consulting engineers were asked to report as to the best means of extending the undertaking, having regard to the demand already made by large works and to the probable future demand from all sources, and both reports discuss the alternatives of extending the present power station, or building a new and supplementary station. Sir John Snell emphatically advises the Corporation on no account to remodel or to extend permanently the existing power-house at East Bridge Street, but to build a new station on a site already acquired from the Harbour Commissioners, and to adopt the three-phase high-pressure system. Sir John also advises the immediate purchase of a 8,000-kw. turbo-alternator, surface-condenser, and pumps, together with a second 1,000-kw. rotary-converter, one being now on order. The latter are to be installed at East Bridge Street, and if the turbo-alternator is ordered now, it could be erected in its permanent position on the new site by the autumn of next year. In Sir John's opinion any extension at East Bridge Street would only postpone the necessity for a second power-house at the least for two years.

Mr. Pratten's report deals more in detail with the possibility of extending East Bridge Street, but he points out that if the Council wish to pursue their policy of encouraging manufacturers to take current, and to supply at a very low rate per unit, there is no other course but to build a new three-phase power-house with 6,000-volt turbo-generators.

If, on the other hand, extensions are decided upon at East Bridge Street and the new power station not proceeded with, he recommends that some of the older Belliss engines should be replaced with turbo-alternators, and a new 1,000-kw. turbo-generator added. The substitution of six Lancashire boilers by four Babcock and Wilcox boilers also would enable an additional 2,000 kw. of generating machinery to be run. This alteration, however, would make the buildings very congested, and no further increase of plant could be carried out at East Bridge Street. Incidentally, the maintenance of the plant at East Bridge Street and the general management is spoken highly of in both reports.

Sir John Snell also deals briefly with the question of costs and charges. The average cost of power, assuming the load-factor of power consumers to vary between 20 per cent. and 25 per cent., is from 0.9846d. to 0.8615d. per unit., and the average receipt is 1.159d. per unit. Some of the large

power users with load-factors of, say, 30 per cent. would only cost 0.78d. per unit, and mills, which usually give a load-factor of 50 per cent., could be supplied, even under present conditions, at 0.6d., and when the three-phase high-tension scheme is ready could certainly be supplied with a margin of profit at even a less figure. Heating could be supplied without loss at an average of  $\frac{1}{2}$ d. even now. With the exception of the small item of public lighting Sir John thinks the whole system of charging has been established on a very sound and business-like footing.

The reports are at present under consideration by the Tramways and Electricity Committee.

### TRADING WITH THE ENEMY

IN connection with the Government Proclamation as to Trading with the Enemy, concerning which we made some comments on page 502 of our issue for September 17th, we have received a document from the British Engineers' Association setting forth the opinions of the Council of that body. These largely coincide with the original resolutions of the B.E.A.M.A., set out on page 514 of our last issue. The Council of the British Engineers' Association, which, by the way, represents British manufacturing engineers, with a combined capital of over £100,000,000, and was formed with the object of fostering British trade with China, has been moved to act in the matter by the receipt of more than 200 communications from its members and from engineering firms outside the Association asking for advice in the matter. Complaint is made that the general effect of the Proclamation not only permits alien enemies in this country to trade, thereby keeping their "goodwill" alive during the war, to the permanent detriment of the business of *bond fide* British firms, but opens a means of passing money from Great Britain to Germany and Austria at a time when that money will be used to prolong the war. Attention is also called to the fact that goods from existing stocks carried in Germany and Austria can actually be procured in Great Britain at the present day through a neutral country.

On account of, in the Council's opinion, the dangerous effect of this policy, a protest has been addressed to the Government urging the revision of the terms of the Proclamation, so that, at all events, certain Germans and Austrians in this country, and more particularly (a) those who manufacture in Great Britain and (b) those who act as agents for manufacturers in Germany and Austria, should be classed as "enemies." The Council hold the view that a Controller appointed by the High Court should be placed in charge of every manufacturing concern in this country which is owned or controlled by Germans or Austrians, so that no payments can be made by such concerns to individuals or firms in Germany or Austria. The Council also hold the view that all trading with German and Austrian agents in this country should be prohibited.

A definition of the class of individuals and firms located in this country who should be considered as enemies, and with whom it is undesirable to trade, has been laid before the Government on the lines suggested above, the status of such parties, it is suggested, being determined by their actual status on June 1st, 1914. The Council recommends members of the Association not to enter into any sort of trade transaction with individuals or firms who come within the definition outlined, and has collected and filed particulars relating to the constitution of a considerable number of firms in this country who have interests in Germany and Austria. This information, which will be added to, is open for investigation by members.

### THE INSTITUTION OF ELECTRICAL ENGINEERS AND THE WAR

THE Institution of Electrical Engineers has had a busy time in connection with the recruiting of the 500 men which the Institutions of Civil, Electrical, and Mechanical Engineers have been invited by the Lords Commissioners of the Admiralty to obtain for the Divisional Engineer Units and Signal Company of the recently formed Royal Naval Division. Particulars of the detachment were given on page 508 of our issue for September 17th. Practically all the work has fallen upon the Institution, whose whole staff has been more or less engaged upon it. Up to Tuesday some 450 recruits had been passed as medically fit by the doctors, and detachments have been sent off practically daily in three batches to the camp near Martin Mill Station, Kent. It was an advantage that two members of the Institution's bankers, Messrs. Cox, Biddulph & Co., were Justices of the

Peace, and these two gentlemen have attended at the Institution building twice daily for the swearing in of recruits. We believe that the three Institutions have contributed representatives in more or less equal proportions, and there is, of course, little doubt that the full 500 men will be obtained.

Another direction in which the Institution has been of service is in connection with supplying men to fill, temporarily, vacancies upon central station staffs whilst the regular employees are on service. As we mentioned on page 472 of our issue for August 27th, some 1,100 members responded to a circular letter sent out by the Institution, a number many times greater than the requirements so far; central station engineers have availed themselves to a certain extent of the offer of their services, with the result that several men ineligible for military service, and who were out of employment, have been found temporary positions.

### ELECTRIC TRACTION NOTES

Experiments have at last been carried out in Hove with trolley omnibuses. Hitherto all work in this direction under the combined scheme with Brighton, sanctioned by Parliament two years ago, has been carried out in Brighton. The omnibus used by the Hove Corporation is of the double-deck type, which has already been officially sanctioned by the Board of Trade in Brighton. The object of the test, it is stated, was to demonstrate the advantages of the over-running trolley as against the under-running trolley, which has been adopted in Brighton.

The Committee of the Bristol Corporation which has had the question of the purchase of the Tramways Co. under consideration, recommends the Corporation first to negotiate with the Company with regard to terms if the Corporation does not exercise its option to purchase for seven, fourteen, and twenty-one years.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

An article in a recent issue of the *Wireless World* describes the control of fog signals by wireless. The signals, which are placed at various points in the Firth of Clyde, and consist of Stevenson-Moyes gas "guns," in which a charge of acetylene and air is fired at intervals. The gas admission and ignition is quite automatic, and once the gas is turned on the cycle of operations proceeds regularly. All that is required, therefore, is to control the gas valve electrically, so that it can be turned on in time of fog. The needle valve used for the purpose is actuated by two electromagnets, one for opening and the other for closing. These are controlled by a relay working in conjunction with a special form of coherer, which receives the signals through a jigger transformer. The principal feature of the apparatus are the selective synchroniser, by which the apparatus only responds to a particular signal, different signals being employed for the turning on and turning off circuits. A 14-foot receiving aerial of the wires is used, and the transmitting apparatus is of the simplest character, embodying synchronisers of similar nature to the receiving synchronisers for giving the correct signals. One of these fog guns is at work on Rose-nath Patch, and is worked from Gourack. Another is at Fort Matilda, and two more are about to be installed.

A Reuter message from Washington states that permission has been granted for the wireless telegraph station at Sayville, Long Island, to operate commercially with Germany until January 1st, 1915. The station has been operating for some time, but had not been officially sanctioned.

The Direct Spanish Co.'s cable between Falmouth and Bilbao was down on the 23rd ult. and in working order again on the 28th ult.—Montenegro notifies that private telegrams in secret language are not admitted, and they are subject to censorship, delay, and senders' risk.—The cable between St. Jacques and Dason is down.—The Eastern Telegraph Co. and Associated Cos. state that as from October 1st deferred telegrams will be again accepted subject to the reservation that this service may be again suspended when their cables are blocked.

## "ELECTRICAL ENGINEERING" PATENT RECORD

\* (This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published September 24th, 1914

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

22,149/13. **Commutator Connections.** H. MENSFORTH (British Westinghouse Co.). The use in continuous current turbo-generators, &c., of commutator connections consisting of several steel cables side by side. Two figures.

1,238/14. **Current Regulation.** G. P. FINCATO (Milan). This regulator is controlled by the expansion of a metal rod heated by the current. The heated rod acts on a bent lever, which, when a certain small displacement has been produced effects a sudden movement of a system of springs connected to the contact which it is desired to open or close. Two figures.

3,963/14. **Wireless Telegraphy.** J. A. FLEMING. A high-frequency oscillation generator, consisting of one or more arcs in shunt with a condenser and in series with an inductive resistance. The electrodes consist of carbon rods in a copper enclosing cylinder open at one end, and nearly closed at the other, and both held vertically in a vessel containing high flash point oil. One figure.

6,350/14. **Searchlights.** W. E. GRAY and W. BEST. Arc lamps for projectors with the feed mechanism worked by an electric motor coupled to its gearing through a centrifugal clutch so that it can start up unloaded. Two figures.

### Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these Patents will appear in our next issue.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** B.T.H. Co. (G.E. Co., U.S.A.) [Distribution system] 22,420/13.

**Switchgear, Fuses and Fittings:** NICHOLLS [Illuminated signs] 1,561/14; HOLOPHONE, LTD. and MYGATT [Metal cover for prismatic reflectors] 4,677/14.

**Telephony and Telegraphy:** STELJES [Morse apparatus] 20,269/13; DE BERNOCHI [Wireless type printing telegraph] 3,371/13.

**Traction:** COLAS [Contacts for traction circuits] 26,268/13.

**Miscellaneous:** DARMOIS and LEBLANC [Vapour electric apparatus] 20,821/13; CAMPBELL [Electrically driven ash hoist] 20,853/13; WIDEGREN and WIDEGREN [Reduction of capacity of line in remote control system] 29,239/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Electrometallurgy:** MASCHINENFABRIK SÜRTH GES. [Electrolytic apparatus] 8,367/14.

**Telephony:** SEELAU and another [Receiver and transmitter with phonographic styles] 14,441/14.

**Incandescent Lamps:** LANGMUIR, 17,326/14.

### Applications for Suspension of Patents

12,871/13. **Electric Ignition.** W. RUTHARDT (Stuttgart). An application for suspension of this patent made by C. A. Vandervell and Co. will be heard on October 7th. The Patent is for timing devices in magneto ignition gear in which the part carrying the contact to be displaced angularly is moved positively in one direction but tends to return in the other direction by the action of a helical spring lying in an annular groove in the movable part.

20,922/12. **Magnetic Clutches.** VULCAN MASCHINENFABRIKS A.G. and 23,150/12, **Switches for Magnetic Clutches.** E. C. R. MARKS (Vulcan Maschinfabriks A.G.). Applications by Glenfield and Kennedy, Ltd., for the suspension of these patents will be heard on October 8th. The improvements in magnetic clutches in question involve a way of making the rim of the armature with a thinned edge to reduce inertia without reducing the area of the field required for the magnetic flux. The switches are of the reversing type suitable for planing machine control.

### Opposition to Grant of Patents

26,764/13. **Conduit Joint.** J. B. A. HEMMING. Opposition has been entered to a grant on this application, covering a continuity grip in which a set screw through a lug in the socket has a portion of its thread cut away in boring out the socket so that a quarter turn is sufficient to cause it to engage with the tube when inserted. This grip was described in ELECTRICAL ENGINEERING, June 18th, page 351.

### Amendments Made

10,373/13. **Electrical Drive of Jacquard Machine.** G. CORSI (Milan). This specification has been amended by several verbal alterations and the substitution of two new claims for the original four.

11,784/13. **Vacuum Cleaners.** M. S. WRIGHT. This specification has been amended by way of disclaimer.

### Expiring and Expired Patents

The following Patents expire during the current week, after a ~~life~~ of fourteen years:—

17,642/00. **Thermal Galvanometer.** W. B. DUDELL. An instrument for measuring small currents and potential differences consisting of a radio micrometer combined with a resistance heated by the current to be measured.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** GEB. SIEMENS & Co. [Searchlight carbons] 13,071/07; H. T. HARRISON and H. HIRST [Flame arc lamps] 13,190/07; GEB. SIEMENS & Co. [Searchlights with curved carbons] 1,316/09; W. R. RIDINGS [Magazine lamps] 13,842/09.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** H. EDMUNDS and P. DAWSON [Couplings for mains] 12,171/06; R. P. JACKSON [Voltage regulation] 12,493/06.

**Ignition:** H. BIRNBACH [Electric gas lighting] 13,417/06.

**Incandescent Lamps:** F. P. DRIVER [Attaching filaments to leading in wires] 13,354/07; O. KRAUSE [Filament supports] 22,458/09.

**Instruments and Meters:** R. KENNEDY [Meters] 9,254/08.

## "ELECTRICAL ENGINEERING" TRADE SECTION

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**PRINTING PRESS CONTROL.**—A leaflet from the Igranic Electric Co. (144 Queen Victoria Street, E.C.) puts forth the advantages of their well-thought-out systems of control of electrically-driven machinery, very opportunely at a time when many newspaper machines are working their hardest.

**METAL FILAMENT.**—A list of Auriga lamps from the British Westinghouse Electric & Manufacturing Co. (Trafford Park, Manchester) contains particulars of half-watt and ordinary standard as well as special metal filament lamps, and is accompanied by the welcome statement that they are British-made.

**SHAFT SIGNALLING FOR MINES.**—A pamphlet from the Sterling Telephone & Electric Co., Ltd. (210-211 Totten-

ham Court Road) describes the Sterling shaft-signalling system for mines, designed to comply with the Home Office requirements in providing an automatic visual indication of the nature of the signal until it is complied with. A luminous indicator is used in combination with an arrangement of bells, relays, and signalling keys.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

**CONTINUOUS CURRENT MOTORS.**—A new list of their latest designs of protected type continuous current motors up to 50 h.p. has been issued by Crompton & Co., Ltd. (Chelmsford). A large range of standard sizes are listed in a convenient way, so that the price of a motor for any output and speed can easily be picked out.

**ELECTRIC PUMPING PLANT.**—The British Electric Plant Co., Ltd. (Alloa), manufacture both centrifugal pumps and special high-speed motors for driving them, and have just issued an interesting pamphlet describing combined sets of this nature, including portable and other pumps of both the horizontal and vertical patterns, and special centrifugal boiler feed pumps.

### THE LIGHTING OF A PROVINCIAL CINEMA

WE have on various occasions illustrated examples of indirect lighting as carried out on the British Thomson-Houston Co.'s "Eye-Rest" system, in cinematograph theatres of the larger and more palatial type. We are now able to illustrate an example of an installation of this kind at a smaller provincial house.

The main portion of the auditorium at the Empire Cinema, Rugby, measures 84 ft. by 40 ft., and the ceiling is 28 ft. high. It is lighted by a single 24-in. "Eye-Rest" brass bowl fitting, containing ten 80-watt Mazda lamps in X-ray reflectors. Over the balcony, which is 84 ft. by 24 ft., there are two 18 in. "Eye-Rest" fittings, each containing three 60-watt Mazda lamps. The space underneath the balcony is lighted by two similarly equipped fittings. The total wattage in the auditorium is thus 1520 watts, which is not excessive, considering the area of the hall and the quality of the illumination. All the auditorium lights are controlled by a single-plate metallic dimmer installed in the operator's

THE EMPIRE CINEMA, RUGBY.

box. The vestibule is illuminated by a single 100-watt Mazda lamp in an intensive type Veluria glass reflector; and a 60-watt lamp similarly equipped is used in the manager's office. Mazda lamps and Mazdalux metal reflectors are used in the pay-box and power-room. The exterior lighting, which is an important feature from an advertising point of view, is carried out by three 600-watt Mazda lamps in intensive Veluria reflectors attached to wall brackets. The British Thomson-Houston Co. also supplied the motor-generator, which consists of a squirrel-cage induction motor, running off a three-phase alternating-current supply at 220 volts, 50 cycles, and driving the generator at 940 r.p.m. The generator is rated at 65 volts, 50 to 60 amps., and delivers current to the projector arc. We understand that the proprietors have expressed great satisfaction with the installation. The British Thomson-Houston Co. will be pleased to give full particulars of this and other cinema installations to readers who are interested, and who will write to or call on the Company's Illuminating Engineers' Department, Mazda House, 77 Upper Thames Street, London, E.C.

### ELECTRIC HEATERS

THERE is every prospect that the radiator side of electrical business during the coming winter months will see little falling off, owing to the fact that their economy after the initial outlay will be recognised, and the effects of the war upon buying luxuries will not come into this class of comfort. Also there are bound to be fresh markets opened, owing to the increase in convalescent homes, hospitals, &c., where electric radiators will be more largely used than previously. Fig. 1 shows one of the heater shops of the Edison & Swan United Electric Light Co., Ltd., at Ponders End. The operatives can be seen assembling parts for the "Royal"

An illustration is given in Fig. 2 of the "Royal" heater ("Quartzalite") which is of elegant design in brass of best

FIG. 1.—HEATER SHOP AT EDISWAN WORKS.

FIG. 2.—"ROYAL" QUARTZALITE HEATER.

material specially suitable for use in drawing-rooms, boudoirs, convalescent homes, hospitals, &c.

**British-made Osram Lamps.**—In last week's *ELECTRICAL ENGINEERING* (page 512) we published an illustrated description of the Osram lamp works at Hammersmith. A further opportunity of making ourselves familiar with the manifold processes which go to make the modern metal filament lamp and satisfying ourselves that they are all (with the possible exception of some of the lamp-caps obtained temporarily from Holland) carried on by British operatives on British soil under British management, was given on Wednesday of last week, when a large and representative body of pressmen were shown every department of the magnificently equipped works at Brook Green. The company already prepare tungsten metal from the ore, and draw the wire at Hammersmith; they have for many years made all their bulbs at Lemington on the Tyne, and it is an open secret that before long they will make their own lamp-caps. We saw "half-watts" being made, as well as ordinary and special Osram lamps. Lunch, at which many guests were entertained, was presided over by Mr. E. Byng, and among the few speeches that were made, the Mayor of Hammersmith, Mr. H. Forman, expressed his gratitude to the Osram and Robertson lamp works for the great benefits and prosperity they had brought to his Borough. Mr. Chris. Wilson, the deservedly popular manager, explained how the Osram works had grown up out of the original Robertson works established twenty-one years ago, and refuted all charges that the business was in any way German, otherwise than that they had picked the brains of Germans and Austrians, as well as of other nations, in developing some of their manufacturing methods. Other speakers showed their appreciation of the patriotism of the firm, and the company broke up well pleased with what they had seen and the lavish hospitality of their hosts. Before lunch an interesting demonstration of the safety of the employees was afforded by the ringing of the fire-bell, when the girls poured out of the huge premises in an incredibly short space of time, while the famous Osram fire brigade got their hoses playing on the building.

## CORRESPONDENCE

## THE B.E.A.M.A. AND THE WAR.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—We notice that in an article on the above subject appearing on p. 514 of your issue of September 24th, you say that the *Electrical Review* was asked by the B.E.A.M.A. not to publish its "State of War" resolutions, but had failed to comply with the request. In view of the fact that no such request was ever made to us by the Association named, or by any of its officials, we must ask you to correct this statement in your next issue.—Yours truly,

4 Ludgate Hill, E.C. H. ALABASTER, GATEHOUSE & Co.  
September 24th, 1914.

[We regret that we should have published the above incorrect statement through a misunderstanding. The B.E.A.M.A. were not desirous that the technical press should publish the resolutions, which had been circulated as a preliminary step to members only, and had not been confirmed; but apparently we were wrong in thinking that the *Electrical Review* had been definitely informed of this. We ourselves took the obviously correct course of asking the Association's permission before publishing the matter at that stage, and we were requested to delay publication. We naturally thought that a similar request had been made to the other technical papers, who, we had understood, had also been in communication with the Association.—Ed. E.E.]

## BELGIAN TRADE.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Will you be so kind as to let your readers know, through the medium of your paper, that, owing to the cessation of the sale of German goods in Belgium, there will be a great demand for British, and we should be pleased to hear from firms supplying armature stamping, brush-holders, carbon brushes, dynamo wires, cables, &c., with a view to represent such firms here.

Thanking you in anticipation, We are,  
21 Rue du Brésil, Antwerp. Yours truly,  
September 21st, 1914. Bugg & Co.

## ARC LAMP CARBONS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to the recent correspondence regarding the scarcity of arc-lamp carbons, we have pleasure in announcing that our works in Switzerland are working day and night, and we are fully capable of executing orders for any quantity of all kinds of arc-lamp carbons as heretofore. The difficulty in procuring raw material has now been overcome, and we are experiencing very little inconvenience as regards shipments.—Yours faithfully,

109-111 New Oxford Street, THE ELECTRICAL ENGINEERING  
London, W.C. & EQUIPMENT CO., LTD.  
Sept. 24, 1914. (CH. LEVEN, Managing Director.)

**Obituary.**—We regret to record the death recently at Rochester, New York State, of Mr. Robert Hope-Jones, M.I.E.E., whose name is so closely associated with the application of electricity to organs. One of the most important inventions in this connection was an organ-stop known as the diaphone. It may also be mentioned that Mr. Robert Hope-Jones was associated with telephony many years ago, and occupied the position of Chief Engineer of the Lancashire and Cheshire Telephone Co. before the National Telephone Co. took it over, and has several inventions to his credit relating to telephony. He was a brother of Mr. F. Hope-Jones of the Synchronome Co.

**The Prince of Wales's Fund.**—The sum of £460, contributed by the employees of Siemens Brothers & Co., at their Woolwich works, has been handed over to the Mayor of Woolwich for forwarding to the Prince of Wales's Fund.

**Foreign Patent Fees.**—The Board of Trade has issued a notice under the Royal Proclamation dealing with Trading with the Enemy, sanctioning the payment of renewal fees upon patents taken out by British subjects in an "enemy country," and also payment, on behalf of an "enemy," of the renewal fees on British patents.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Colwyn Bay.**—Turbo-alternators, water-tube boilers, E.H.T. and L.T. switchgear, cooling tower, crane, power station cables, rotaries and static transformers, substation switchgear, &c. Consulting Engineer, E. H. Lacey, 12 Victoria Street, S.W. October 20th.

**Eastleigh.**—Dr. J. A. Purves of Exeter is to report upon an electric lighting scheme.

**Fleetwood.**—The street electric lighting is to be improved.

**Stockport.**—The Guardians invite tenders from British manufacturers for electric lamps.

**Whitworth (Lancs.).**—Sub-station plant. Town Clerk.

## Wiring

**Dolgelly.**—The Board of Guardians is considering the adoption of electric lighting at the workhouse.

**Edinburgh.**—Electrical fittings for the Midlothian and Peebles District Asylum. Clerk, 19 Heriot Row. October 5th.

**Loughrea.**—Wiring and fitting of workhouse. Consulting Engineer, L. J. Lawless, 27 Castlewood Avenue, Rathmines, Dublin. October 8rd.

**Newmarket.**—Electric lighting of workhouse.

**Swansea.**—Wiring and fitting of new police station. Borough Electrical Engineer. October 5th.

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Blackburn.**—Fire station and firemen's dwellings (£81,600).—Electrification of Greenbank Bobbin Works.

**Chelmsford.**—School, Lady Lane.

**Clones.**—The Guardians have rescinded the resolution postponing the installation of electric light at the workhouse.

**Glasgow.**—Teachers' Training College at Jordanhill (£200,000).

**Folkestone.**—School, Park Road.

**Hull.**—Tuberculosis hospital (£14,498).

**Leicester.**—School.

**Mansfield.**—School.

**Nottingham.**—New school.

**Portrush.**—Public baths (£3,500).

**Port Talbot.**—New hospital. Architect, F. B. Smith.

**Sheffield.**—Children's hospital at the Eccleshall Workhouse (£5,842).

**Taunton.**—Small-pox hospital.

**Tynemouth.**—Elementary schools, Spring Gardens. Architect, A. K. Tasker, Education Offices, North Shields.

## TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

**Belfast.**—The Corporation has decided to purchase an electric motor tower waggon from the Edison Accumulators, Ltd.

An important contract has been placed with the General Electric Co. for the electrical equipment of the York Street Flax Spinning Co.'s works. Individual drive is to be applied to the spinning frames.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Although the Metal Exchange is not open for business in the ordinary course, the following may be taken as the official quotation for electrolytic copper bars, viz., £57 to £57 10s. (Last week, £54 10s. to £55.)

**Canadian Agency.**—A Montreal company dealing in electrical supplies desired to be placed in communication with United Kingdom manufacturers of tungsten and carbon fila-

ment lamps, arc-lamp carbons, and street-lamp fittings. The name of the company may be obtained at 73 Basinghall Street, E.C.

**The Lighting Journal.**—We are asked to state that the offices of the Lighting Press Syndicate, Ltd., have been transferred to 37 and 38 Strand. Mr. A. J. Greenly has taken over the management of both the editorial and business departments.

**Change of Address.**—The advertising business conducted by Mr. Arthur J. Greenly has been transferred from 3 Victoria Street to 37 and 38 Strand.

## LOCAL NOTES

**Aberdeen: Increased Profit.**—The net profit on last year's working of the electricity undertaking was £4,960, an increase of £2,725 over the previous twelve months. This result has been obtained notwithstanding coal having cost 1s. 4d. per ton more than in the previous year; and is attributed entirely to the more efficient generating plant which has been installed at the Ferryhill power station. This includes a 8,000-kw. turbo-alternator installed in December, which has generated 5,081,400 units out of 6,861,860 units output since it was started up.

**Arbroath: Assessment of Electricity Works.**—The present assessment of the works of the Arbroath Electric Light & Power Co. is on the basis of £688 for works and generating station, and £532 for mains within the burgh. The Company last week appealed against this assessment and asked for it to be reduced to a total of £500, viz., £280 for works and £220 for mains. On the other hand, the Assessment Committee asked that the value should be increased to £1,470, viz., £827 for works and £643 for mains. It was agreed on both sides that the proper basis of fixing the valuation is revenue, but the question of difference was as to the application of this basis. The Assessment Committee took the revenue of the previous year, whereas the Company claimed that the average of the previous three years should be taken. The Court eventually fixed the total figure at £1,100, and the Company has decided to take the case further.

**Blackrock: Overhead Wires.**—The Council has applied to the Board of Trade for sanction to erect overhead wires in connection with its electric lighting Order, granted in the session just expired.

**Dewsbury: Corporation and Power Co.**—The Yorkshire Electric Power Co. has suggested that the Electricity Committee should consider the adoption of the general principle of co-operation with the Power Co. in relation to the question of the future supply of electricity in the Borough. The Committee has replied, however, that no circumstances have yet arisen which would justify it in following such a course.

**Glasgow: New Power Station.**—Considerable progress has been made with the preliminary building work of the new power station at Dalmarnock. The first section is estimated to cost £250,000.

**Portishead: Overhead Wires.**—The Clevedon, Portishead & District Electric Supply Co. has applied to the Board of Trade for sanction to erect a number of overhead wires for a supply to the South Liberty Colliery at a pressure of 550 volts.

**St. Anne's-on-Sea: Domestic Power Demand.**—The quantity of electricity used per month for domestic power purposes, such as heating, cooking, &c., has doubled itself during the past twelve months. The price of current for these purposes has now been fixed at 1d. per unit.

**Shoreditch: Electricity Accounts.**—There was a net profit on the electricity undertaking last year of £4,769, including £54 brought forward. Of this £1,500 is to be transferred to the relief of rates, and £2,500 to reserve fund. After meeting expenditure on account of change of pressure and the conversion of gas lamps, a balance of £120 is carried forward.

**Skipton: Electric Supply.**—A committee is to be formed to discuss with the Yorkshire Electric Power Co. the question of an electric supply in this district. The Council was one of few authorities which did not object to the Yorkshire Co.'s Bill as presented to Parliament last session. This, however, was drastically redrafted before it finally left Parliament. It would have given the Company powers to supply in Skipton,

but owing to the alterations it will now be necessary to deal with each district separately.

**Southend: Loans Cancelled.**—The Council has asked the L.G.B. to cancel recent applications for sanction to borrow £1,715 and £2,895 for the purposes of the electricity undertaking, as the Accountant has reported that these sums will not now be required.

**Stoke-on-Trent: Loss on Electricity Undertaking.**—There was a loss of £8,162 upon the working of the electricity undertaking last year, but this was foreseen when the estimates for the new power station, which has only been in operation for a short time, were prepared. Included in the deficit is a sum of £1,586 for meters. The number of units sold during the year was seven millions, compared with six millions in the previous twelve months, whilst, of course, the working expenses are debited with a considerable extra expenditure in respect of coal which cost on an average 11s. 10½d. per ton, against 8s. 10d. two years ago. Now that the central power station is in working order, considerable economies will be effected at the various smaller power stations hitherto used.

**Walsall: Loan Postponed.**—Application was to have been made for a further loan of £28,595 for expenditure upon the electricity undertaking. When the matter came before the Council at the last meeting, however, the Chairman of the Electricity Committee said that, having regard to all the circumstances, the Committee had decided to withdraw the application for the present in the hope that money might be obtained on more advantageous terms in the future.

**Warrington: Electricity Accounts.**—There was a net profit of £2,935 upon the past year's working of the electricity undertaking. The output shows satisfactory increase, that for power being no less than 985,488 units in excess of the previous twelve months. The Sales Department has also shown considerable activity during the year, the turn-over being £1,377 and the profit £282. The coal costs show an improvement of 6 per cent. over the previous year's figures, notwithstanding an increase of 4½ per cent. in the price of coal.

**York: Overhead Wires.**—The Corporation has given notice of its intention to apply for sanction to use overhead wires for electric supply purposes in several districts in the rural area.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Nairobi Electric Power & Lighting Co.**—A 6 per cent. dividend is declared on the ordinary shares for the June half year.

**Clyde Valley Electrical Power Co.**—The June half year's accounts show a net profit of £19,297 after meeting preference dividend and transferring £12,500 to contingency fund for depreciation. It is recommended that £1,925 be transferred to special reserve and the balance of £17,372 carried forward.

**Oxford Electric Co.**—An interim dividend at the rate of 5 per cent. per annum is recommended on the ordinary shares for the June half year.

**British Electric Transformer Co.**—An interim dividend at the rate of 6 per cent. is recommended on the ordinary shares for the June half year.

**South London Electric Supply Corporation.**—The 6 per cent. cumulative preference dividend for the half-year to September 30th will be paid on October 1st.

**Bromley (Kent) Electric Light & Power Co.**—An interim dividend at the rate of 4 per cent. per annum, less tax, is declared on the ordinary shares for the past half-year.

**British Insulated & Helsby Cables.**—An interim dividend at the rate of 8 per cent. per annum, less tax, is declared on the ordinary shares for the past half-year.

**British Aluminium Co.**—The half-yearly interim dividend is to be paid on the 6 per cent. preference shares.

**County of Durham Electrical Power Distribution Co.**—The directors announce that they have decided not to declare an interim dividend on the preference shares.

**Electro-Harmonic Society.**—The first smoking concert of the season will be held at Holborn Restaurant (King's Hall) on Friday, October 9th, at 8 p.m. Mr. A. H. Seabrook will take the chair.

## SUMMARY

THE position with regard to the L.B. & S.C. Rly. contract with a German firm for the electrical equipment of new trains is reviewed. (Page 534.)

AN article on Germany's telegraphic isolation explains how completely she is cut off telegraphically from the rest of the world, and of what little advantage to her are her wireless stations. (Page 534.)

THE use of star connected transformers on unbalanced three-phase circuits is discussed in our "Questions and Answers" columns. (Page 535.)

AMONG the subjects of specifications published last week at the Patent Office are mercury vapour apparatus, power-factor regulators, and distance control. A combined glass and metal Holophane shade has also been patented. One of the patents for the construction of the Berry transformer expires this week, after a full life of fourteen years. (Page 536.)

THE St. Pancras Borough Council has objected to a proposal by the L.C.C. that the period of repayment of certain outstanding loans on the electricity undertaking should be reduced by half. (Page 537.)

IN our notes on telegraphy, &c., we report a case of an illicit wireless station and review the possibilities with regard to such an installation.—Several new telegraph cables have been laid across the English Channel. (Page 537.)

AN article on "Trading with the Enemy" deals with a point in connection with the recent proclamation

which seems to have been misunderstood in some quarters, and also mentions arrangements which we have made to facilitate inquiries as to the position of firms so far as foreign capital and control is concerned. (Page 538.)

OTHER articles in our Trade Section deal with new conduit inspection boxes, British-made lamps, and an instrument works near Manchester. (Page 538.)

CABLE is required at Tunbridge Wells and St. Pancras; boilers at Maidstone; sub-station switchgear at Warrington.—Tramway extensions are to be carried out at Leeds and in London. (Page 539.)
